... $2^{43,112,609}-1$ (GIMPS, 2008) ...

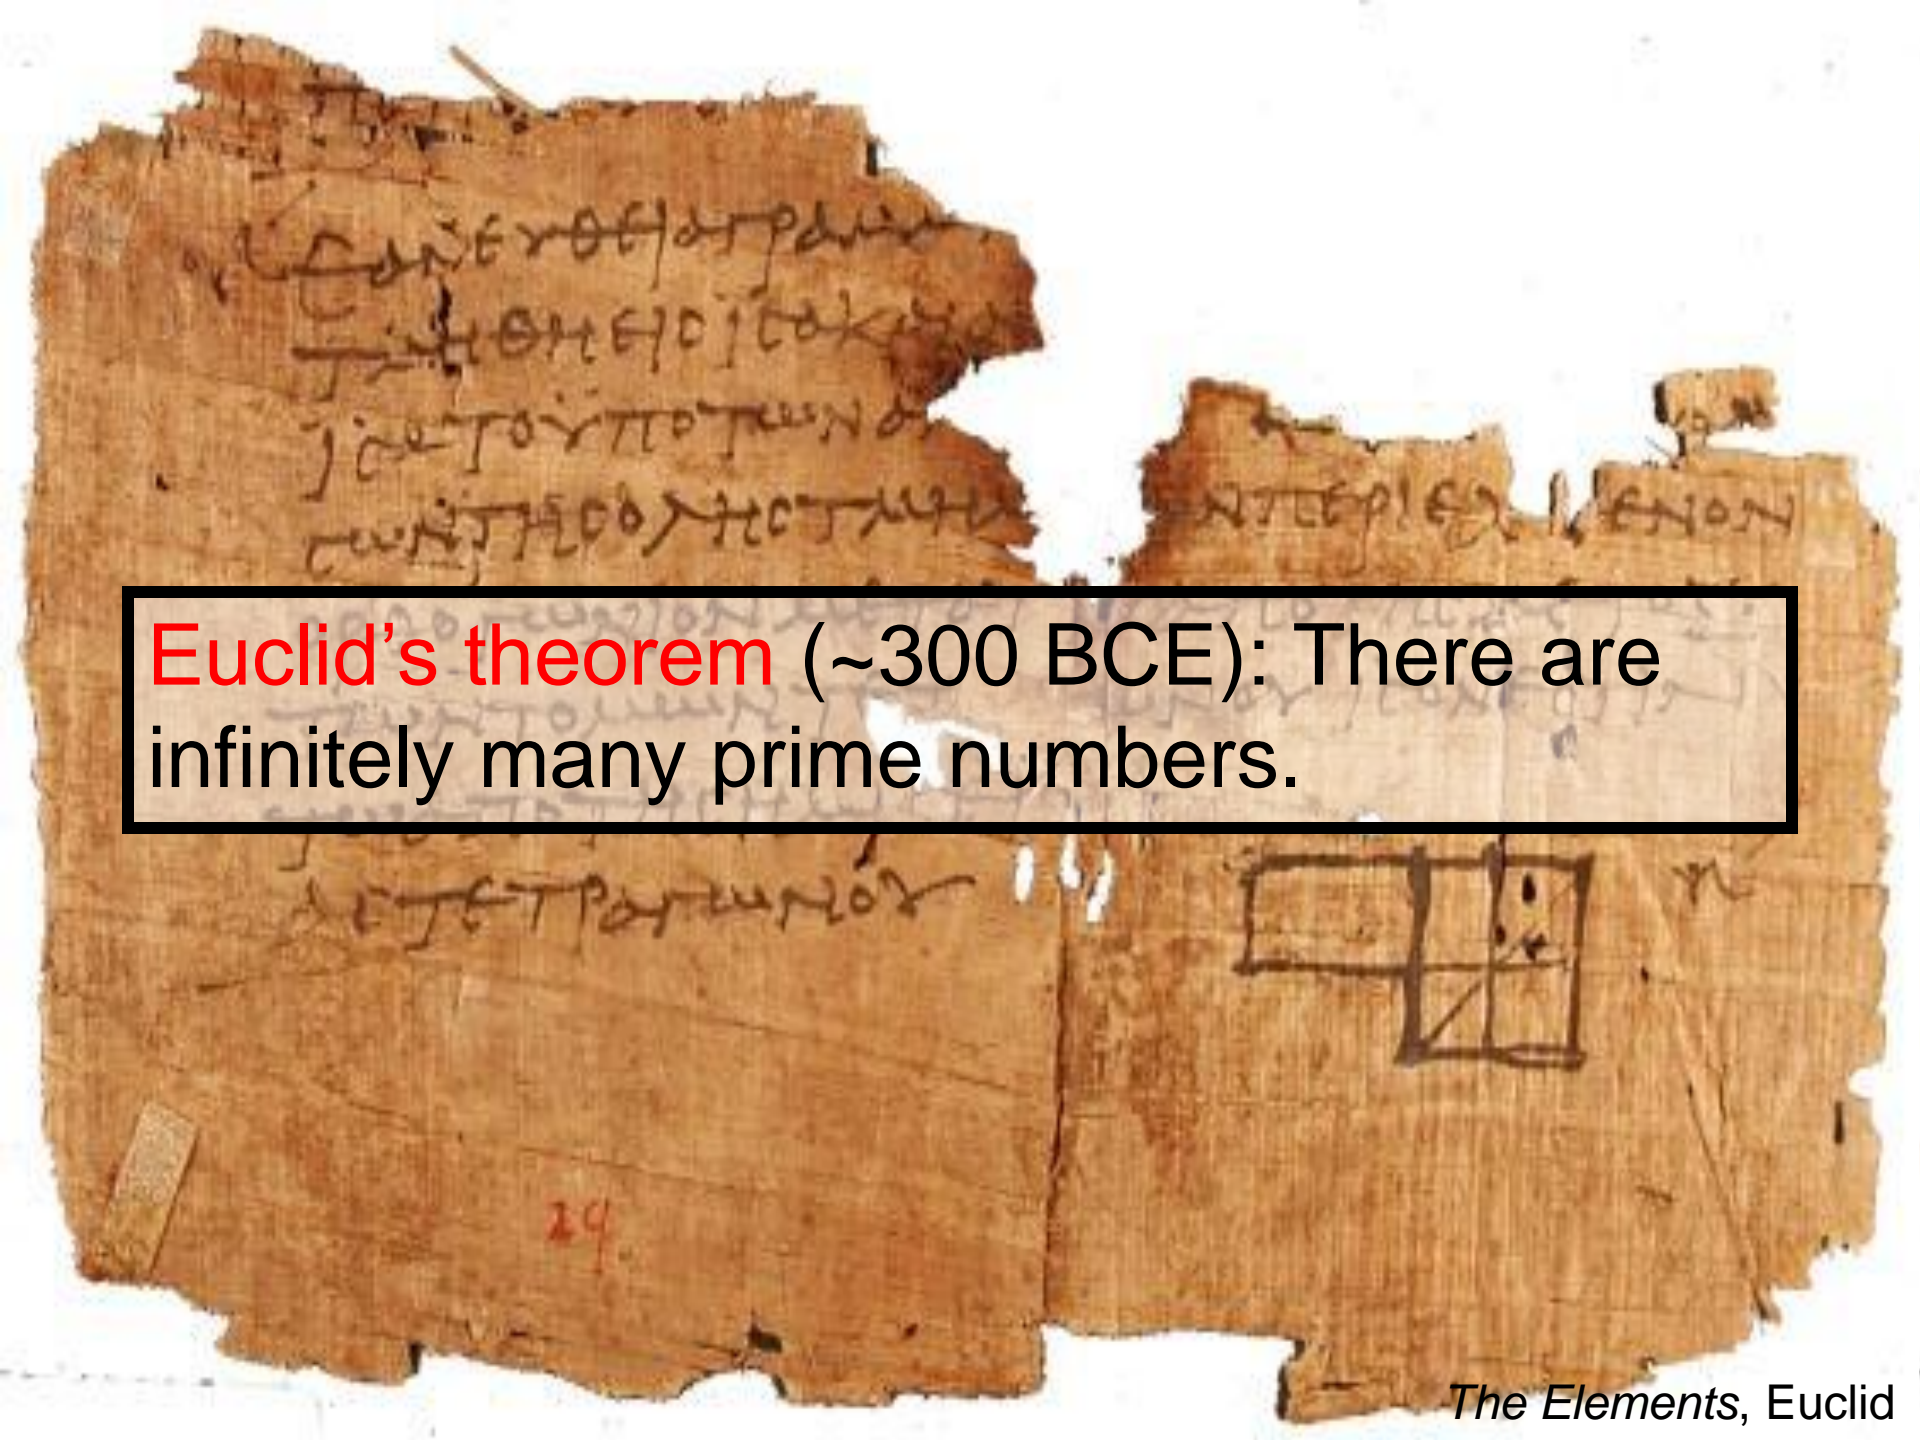

A **prime number** is any natural number greater than 1, which cannot be factored as the product of two smaller numbers.

Prime numbers have been studied since the ancient Greeks. They proved two important results:

Fundamental theorem of arithmetic (~300 BCE): Every natural number greater than 1 can be expressed uniquely as the product of primes (up to rearrangement).

Euclid's theorem (~300 BCE): There are infinitely many prime numbers.

$$98 = 2 * 7 * 7$$

$$99 = 3 * 3 * 11$$

$$100 = 2 * 2 * 5 * 5$$

The **fundamental theorem** tells us that the prime numbers are the “atomic elements” of integer multiplication.

$$101 = 101$$

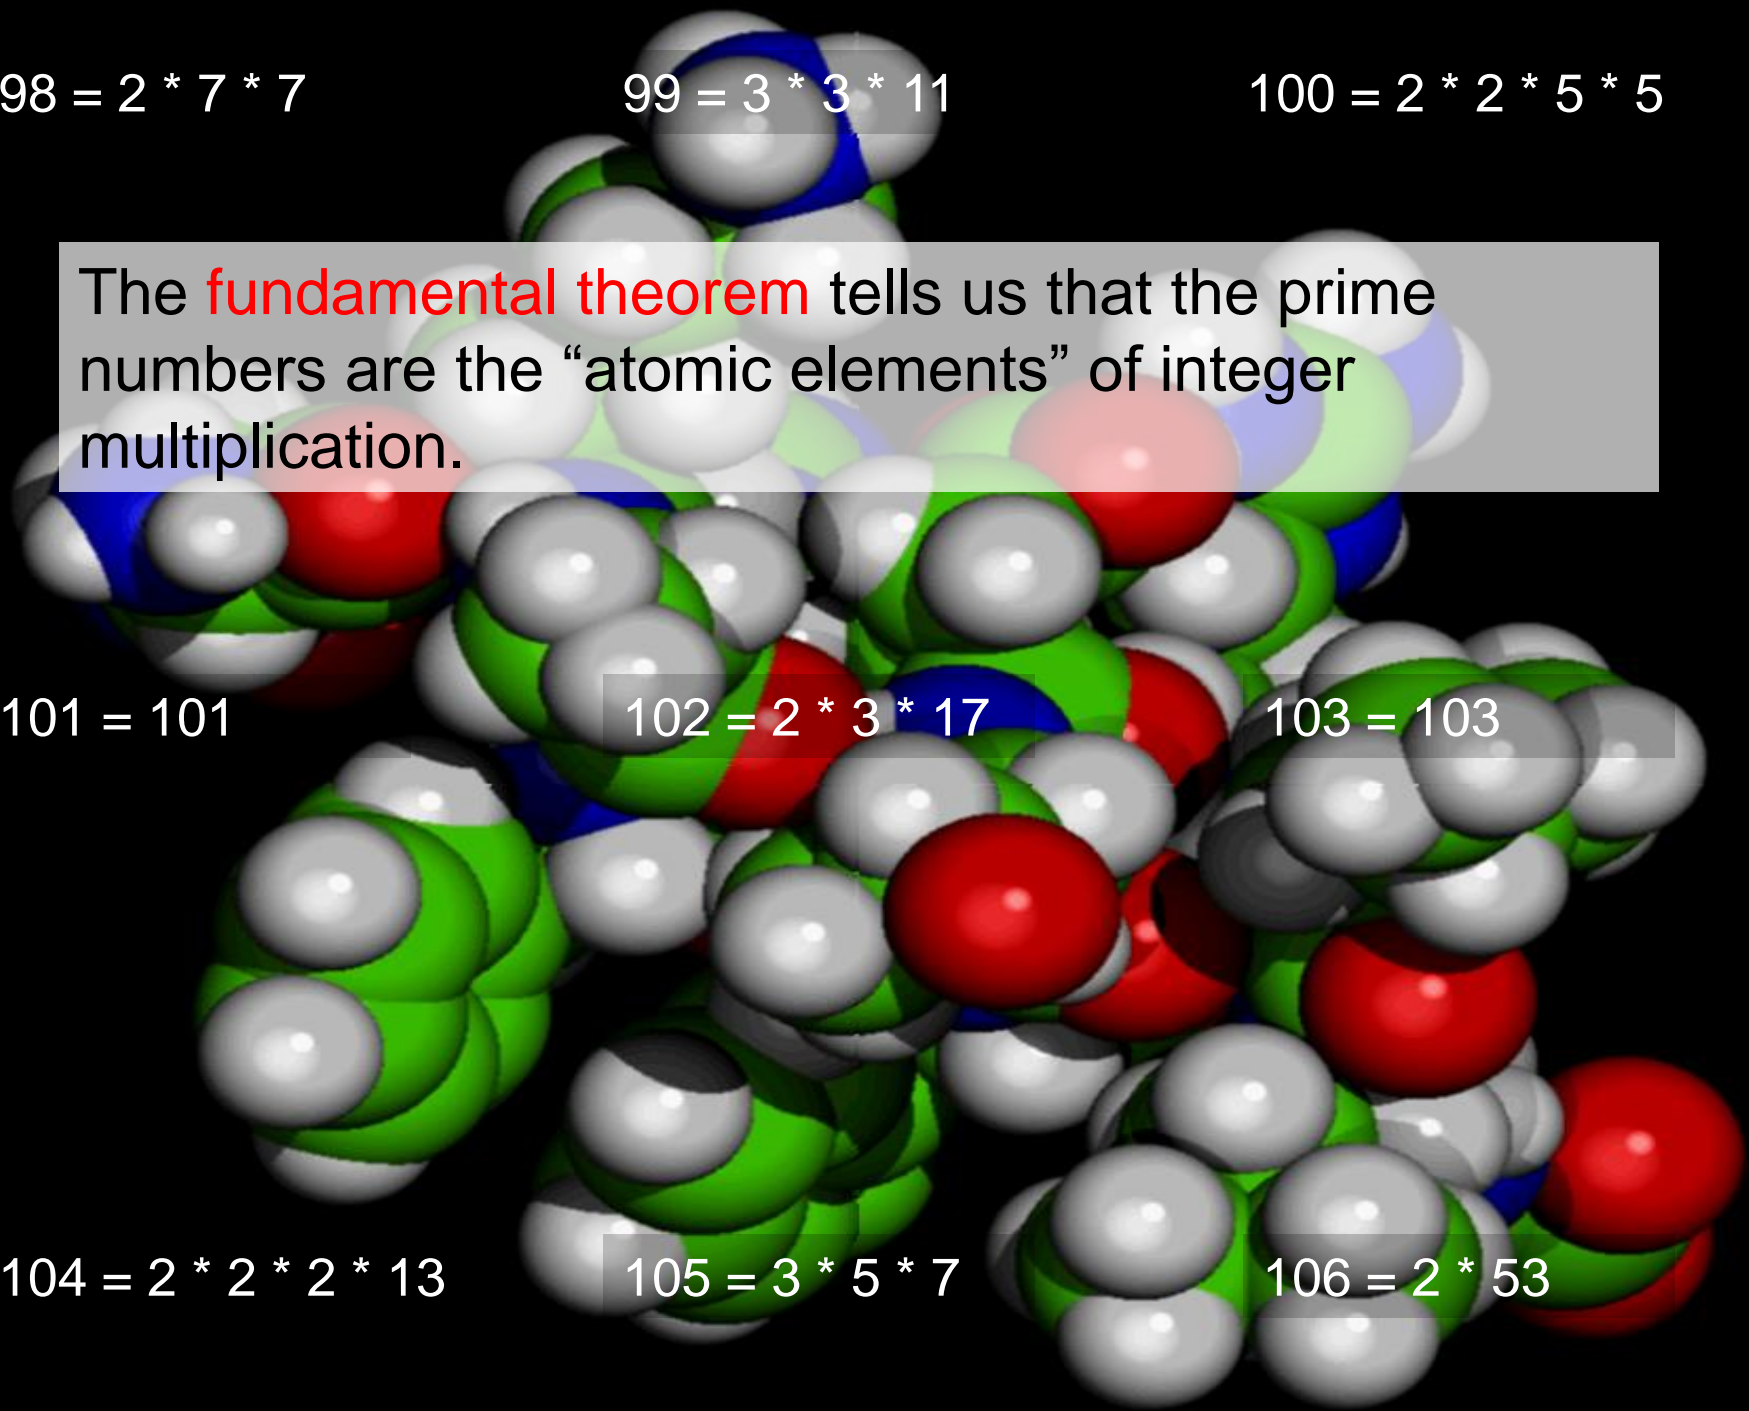

$$102 = 2 * 3 * 17$$

$$103 = 103$$

$$104 = 2 * 2 * 2 * 13$$

$$105 = 3 * 5 * 7$$

$$106 = 2 * 53$$

$$98 = 2 * 7 * 7$$

$$99 = 3 * 3 * 11$$

$$100 = 2 * 2 * 5 * 5$$

It is because of this theorem that we do not consider 1 to be a prime number.

$$101 = 101$$

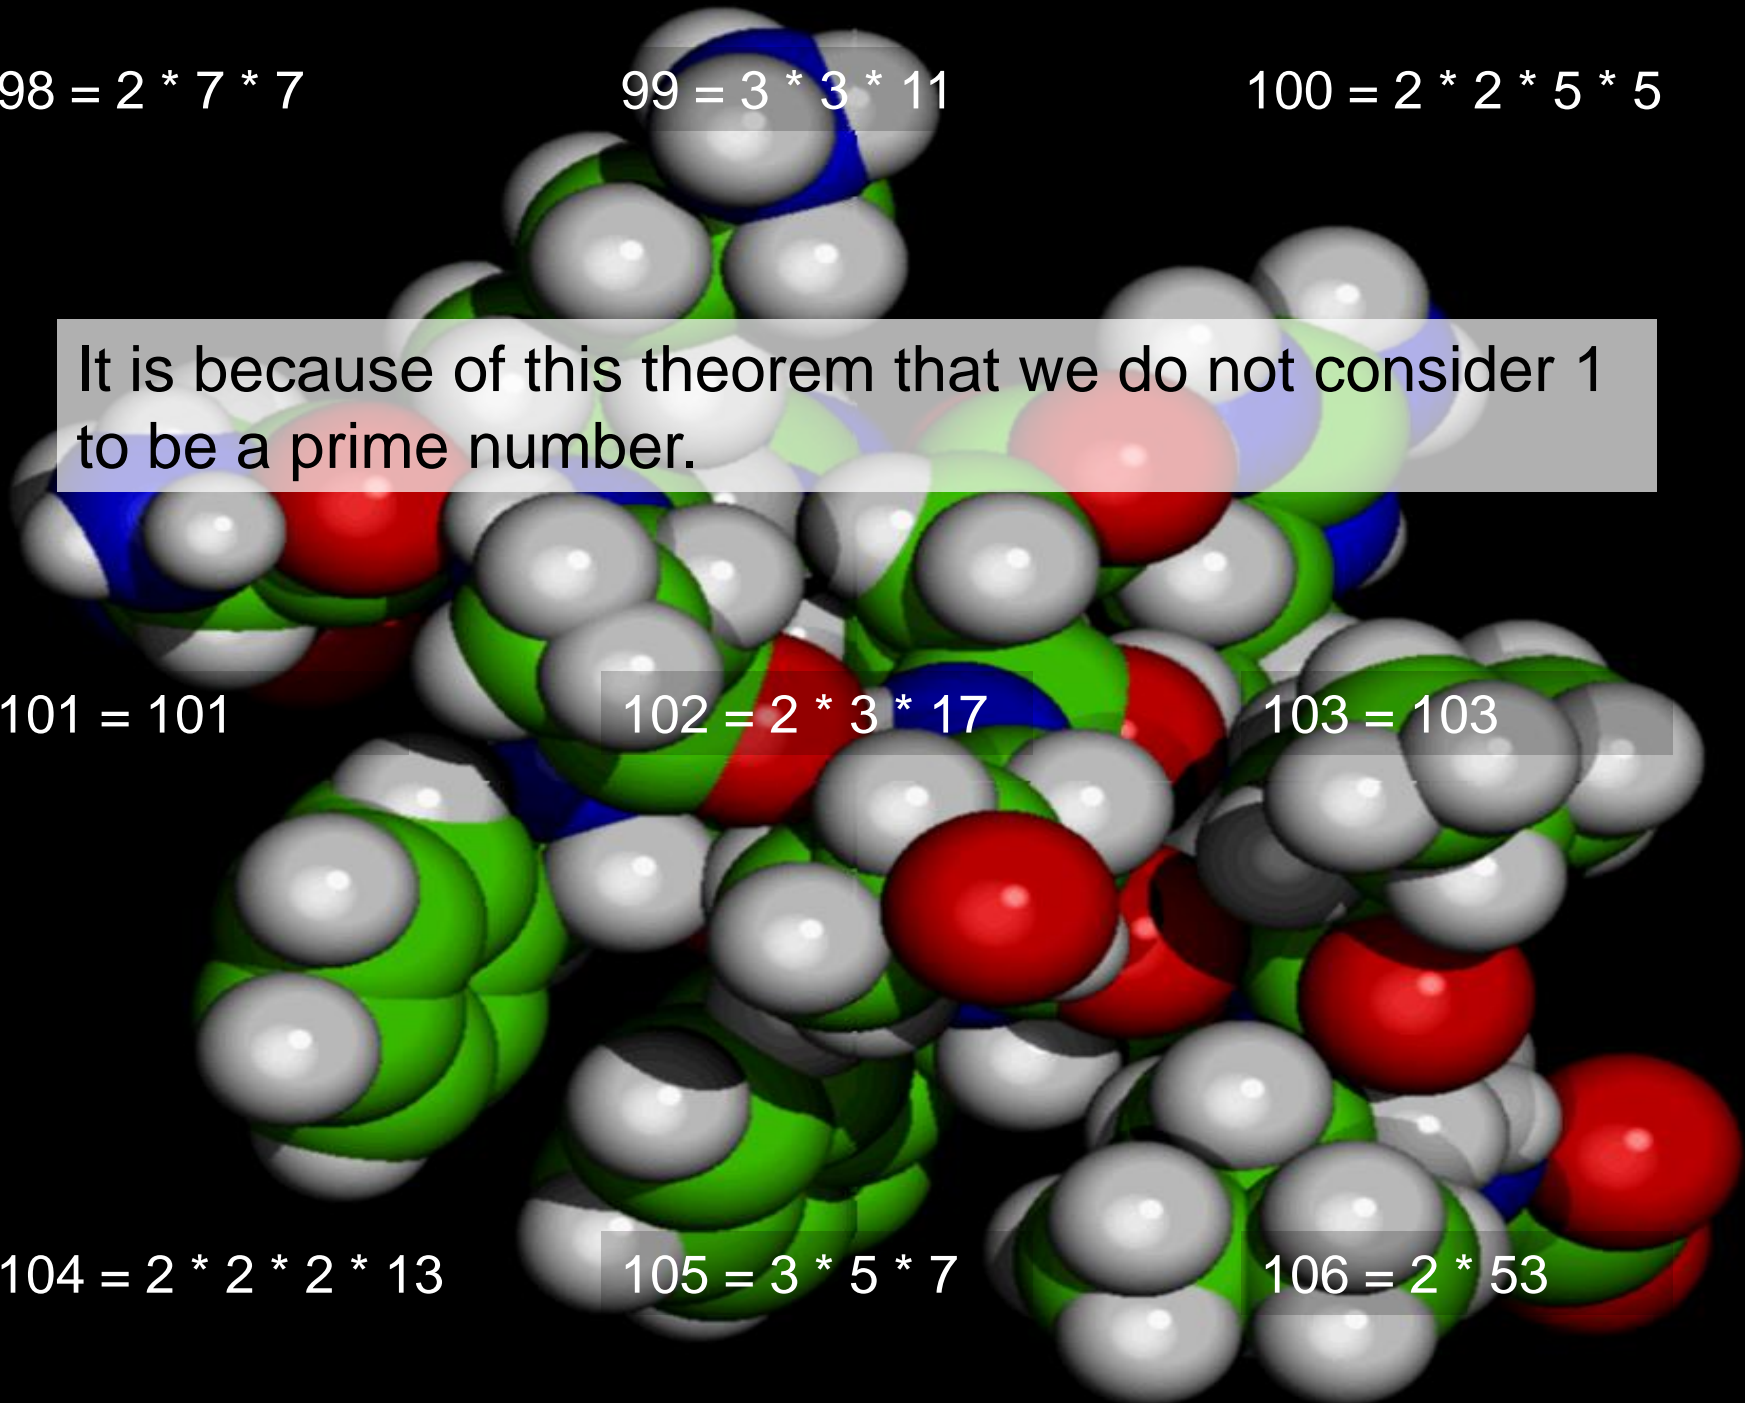

$$102 = 2 * 3 * 17$$

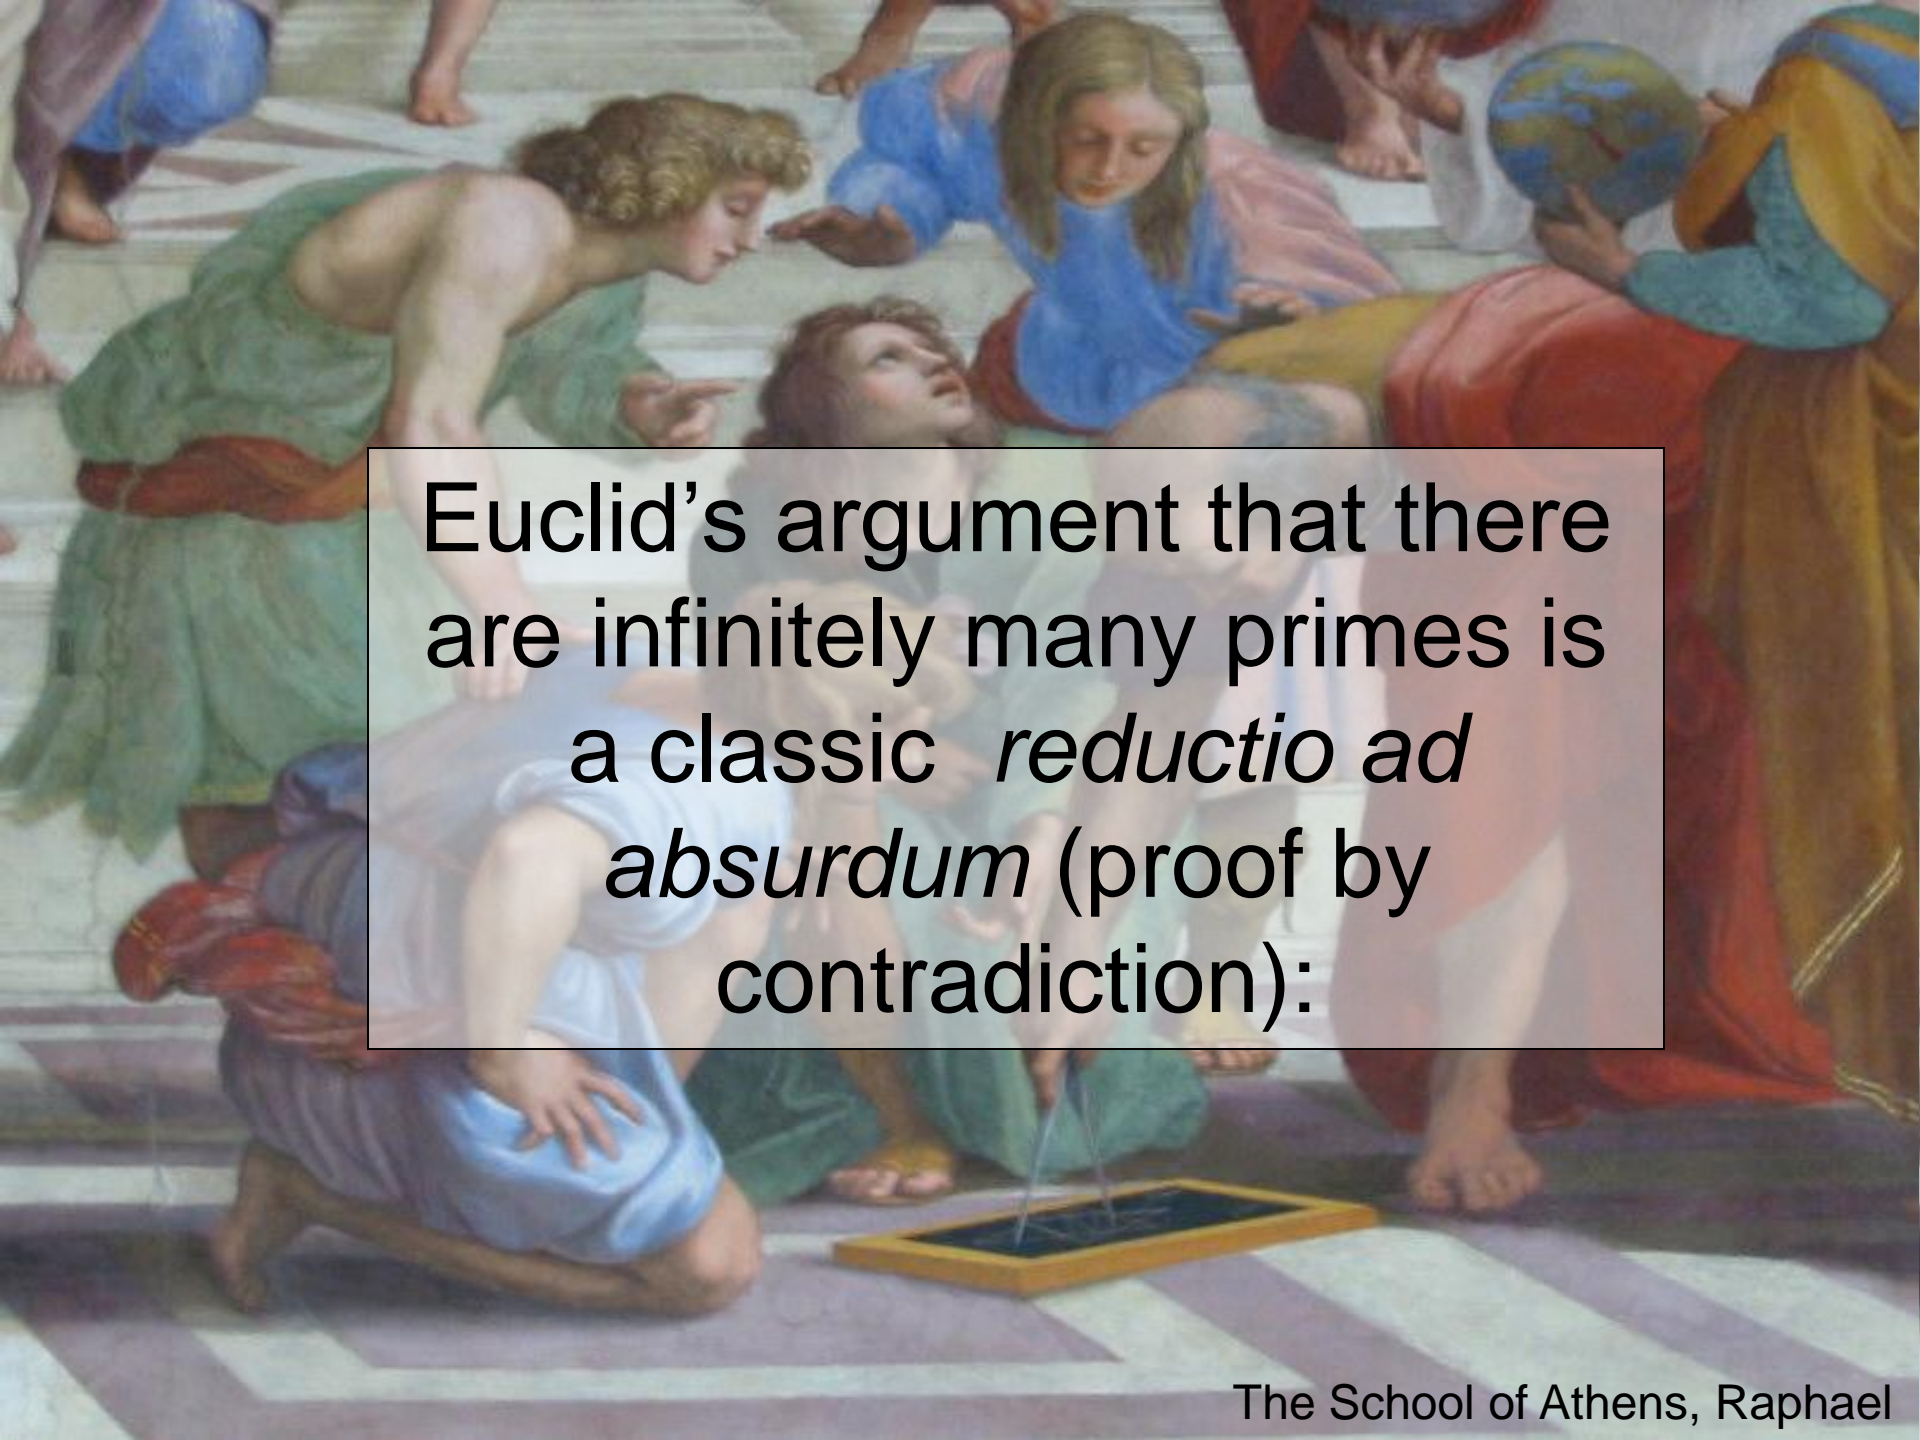

$$103 = 103$$

$$104 = 2 * 2 * 2 * 13$$

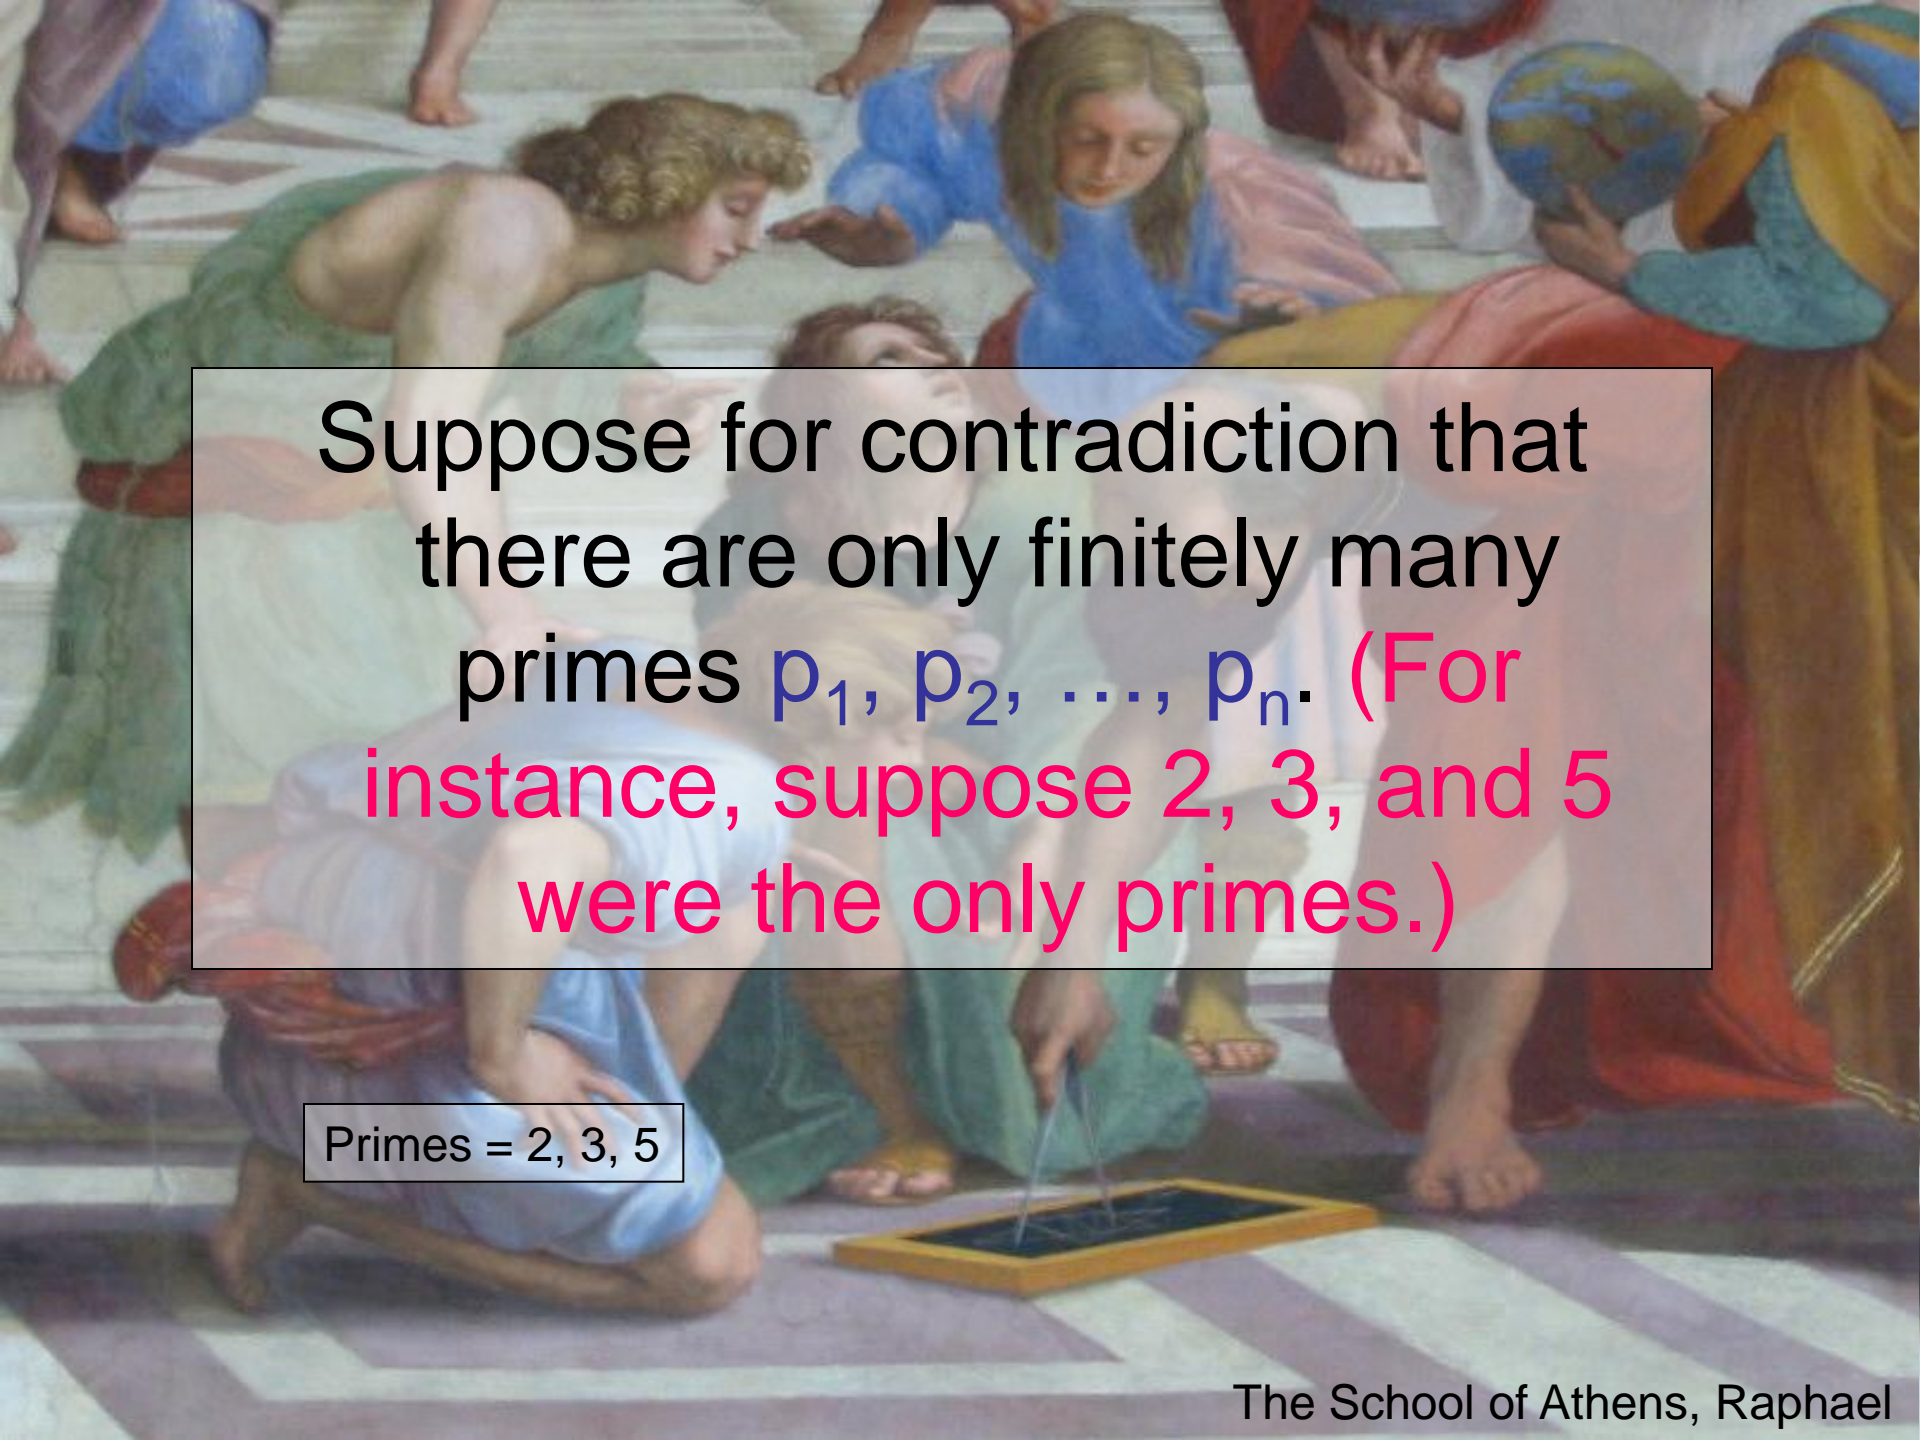

$$105 = 3 * 5 * 7$$

$$106 = 2 * 53$$

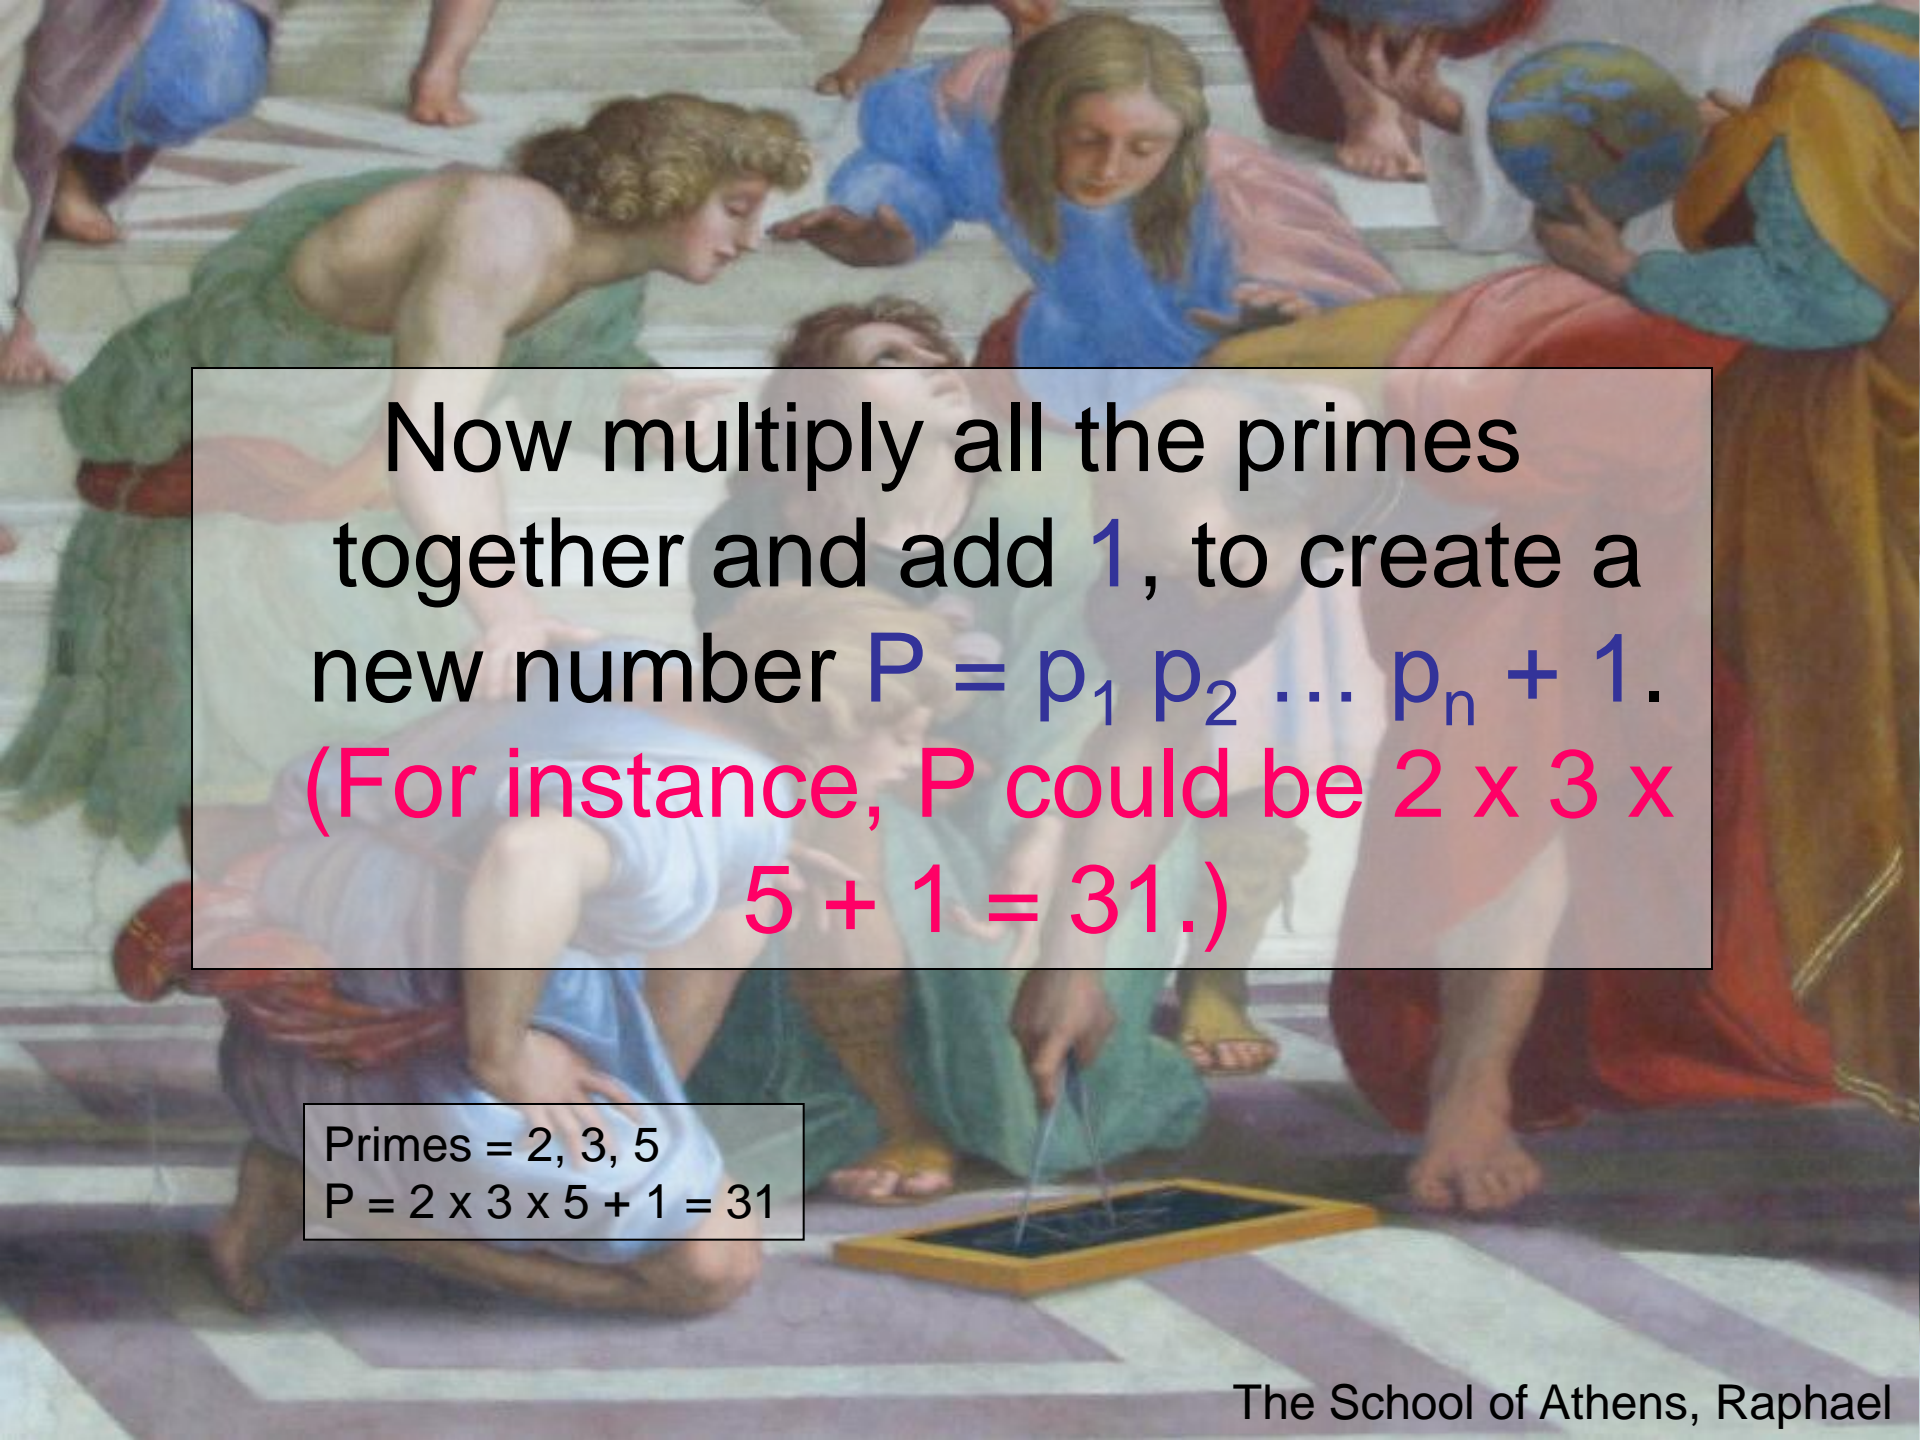

A detail from Raphael's fresco 'The School of Athens'. It depicts Plato on the left, leaning forward and pointing his right index finger towards the sky. He is dressed in a green tunic with a red sash. Aristotle is on the right, kneeling and looking up at Plato. He is dressed in a blue tunic. In the foreground, a wooden tablet with a grid is on the floor, with a quill pen resting on it. Other figures in classical attire are visible in the background, including a woman in a blue dress and a man in a red and yellow robe holding a globe.

Euclid's argument that there are infinitely many primes is a classic *reductio ad absurdum* (proof by contradiction):

The background of the slide is a detail from Raphael's fresco 'The School of Athens'. It shows several figures in classical attire. In the foreground, a man in a blue tunic is kneeling and drawing a grid on a tablet on the floor with a compass. To his left, another man in a green tunic is leaning forward, looking at the drawing. In the background, a woman in a blue tunic is looking down at the drawing, and another woman in a red tunic is holding a globe. The scene is set on a tiled floor with a purple and white striped pattern.

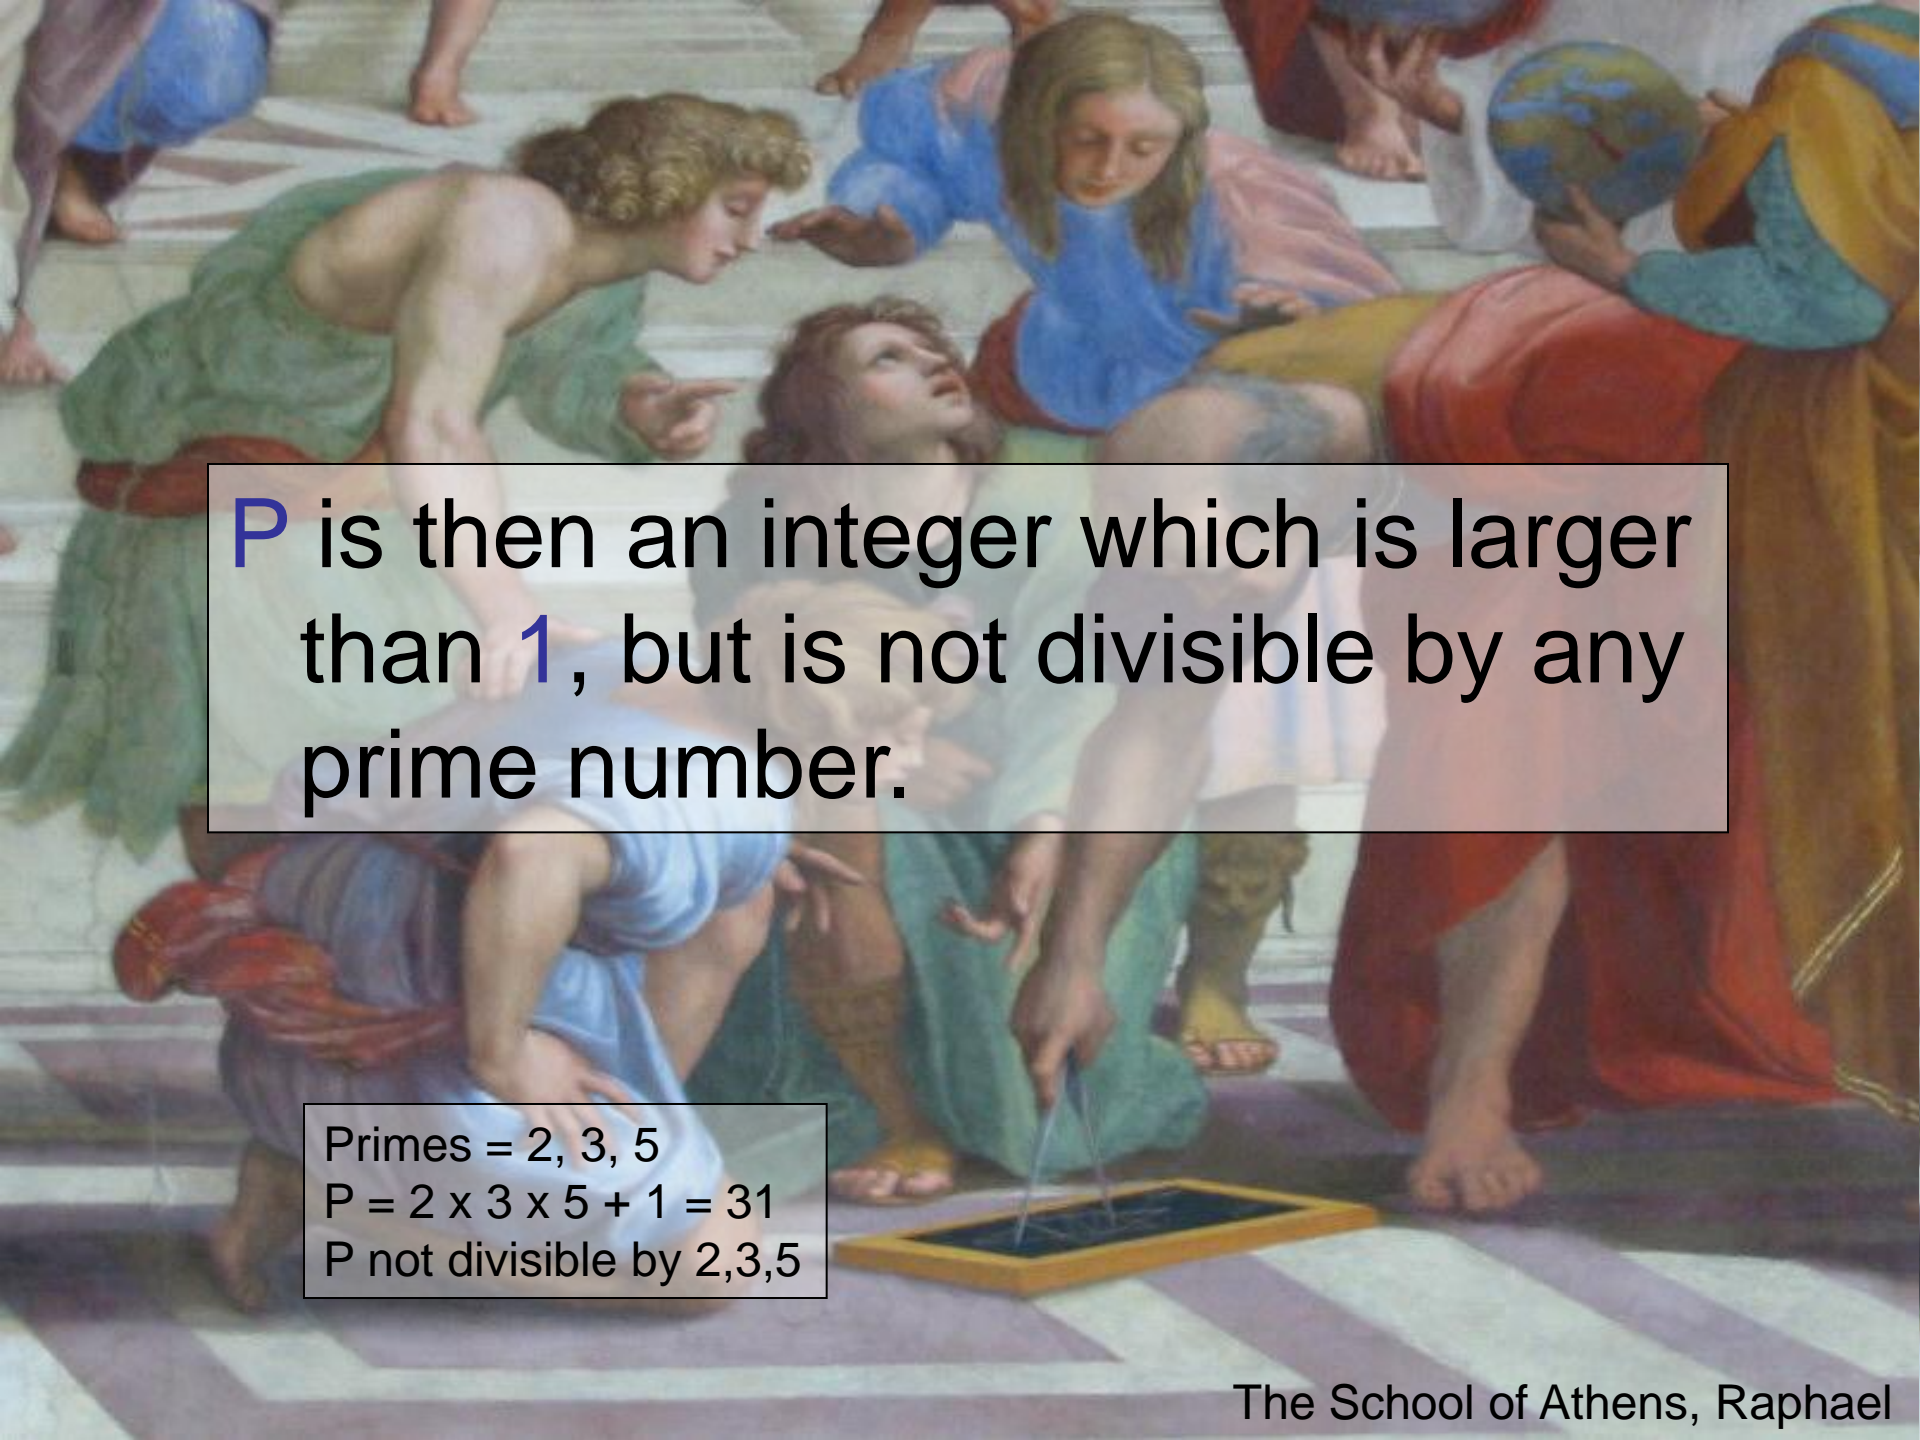

Suppose for contradiction that there are only finitely many primes p_1, p_2, \dots, p_n . (For instance, suppose 2, 3, and 5 were the only primes.)

Primes = 2, 3, 5

A detail from Raphael's fresco 'The School of Athens'. It shows Plato on the left, pointing upwards, and Aristotle on the right, gesturing downwards. They are surrounded by other figures in classical attire. The scene is set on a checkered floor.

Now multiply all the primes together and add 1, to create a new number $P = p_1 p_2 \dots p_n + 1$.
(For instance, P could be $2 \times 3 \times 5 + 1 = 31$.)

Primes = 2, 3, 5
 $P = 2 \times 3 \times 5 + 1 = 31$

A detail from Raphael's fresco 'The School of Athens'. It shows Plato on the left, pointing upwards, and Aristotle on the right, gesturing downwards. They are surrounded by other figures, including a woman in a blue dress and a man in a red and yellow robe. The scene is set on a checkered floor.

P is then an integer which is larger than **1**, but is not divisible by any prime number.

Primes = 2, 3, 5
 $P = 2 \times 3 \times 5 + 1 = 31$
P not divisible by 2,3,5

A detail from Raphael's fresco 'The School of Athens'. It shows Plato on the left, leaning forward and pointing his right index finger towards the sky. He is wearing a green tunic. Aristotle is on the right, sitting on the ground and looking up at Plato. He is wearing a blue tunic and a red cloak. In the foreground, a woman in a blue tunic is kneeling and writing on a tablet with a stylus. The floor is tiled with a geometric pattern.

But this contradicts the
**fundamental theorem of
arithmetic.** Hence there must be
infinitely many primes. \square

Primes = 2, 3, 5
 $P = 2 \times 3 \times 5 + 1 = 31$
P not divisible by 2,3,5
Contradiction!

“Reductio ad absurdum, which Euclid loved so much, is one of a mathematician's finest weapons. It is a far finer gambit than any chess gambit: a chess player may offer the sacrifice of a pawn or even a piece, but a mathematician offers the game ”.

([G.H. Hardy](#), 1877-1947)

Generated in pairs

The **fundamental theorem** tells us that every number can **in principle** be factored into primes – but **nobody** knows how to factor large numbers rapidly!

Secret

+

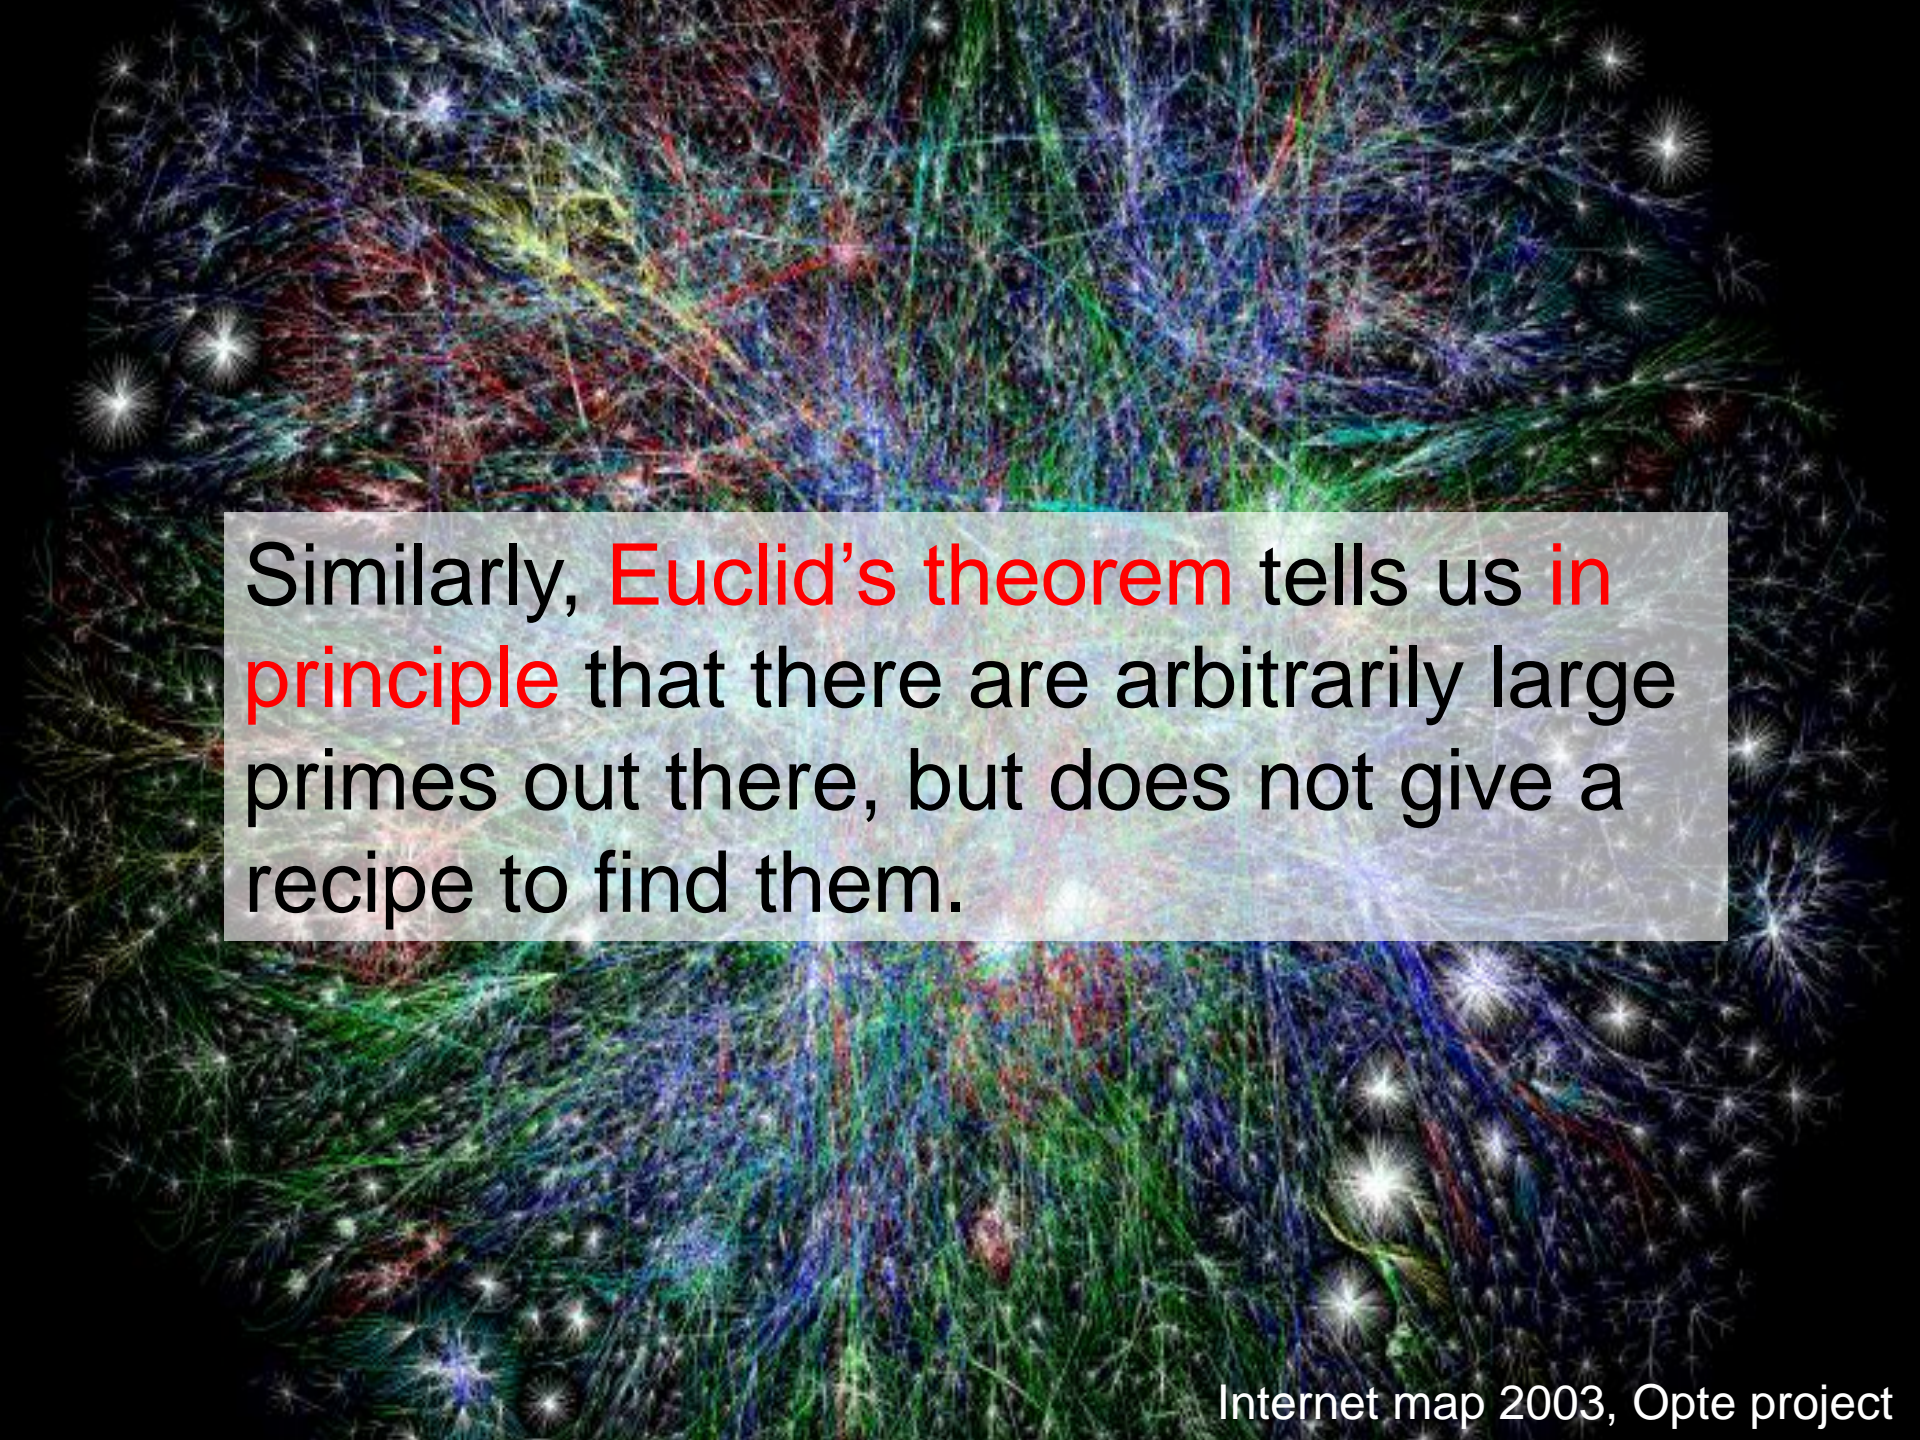

Encrypted

-

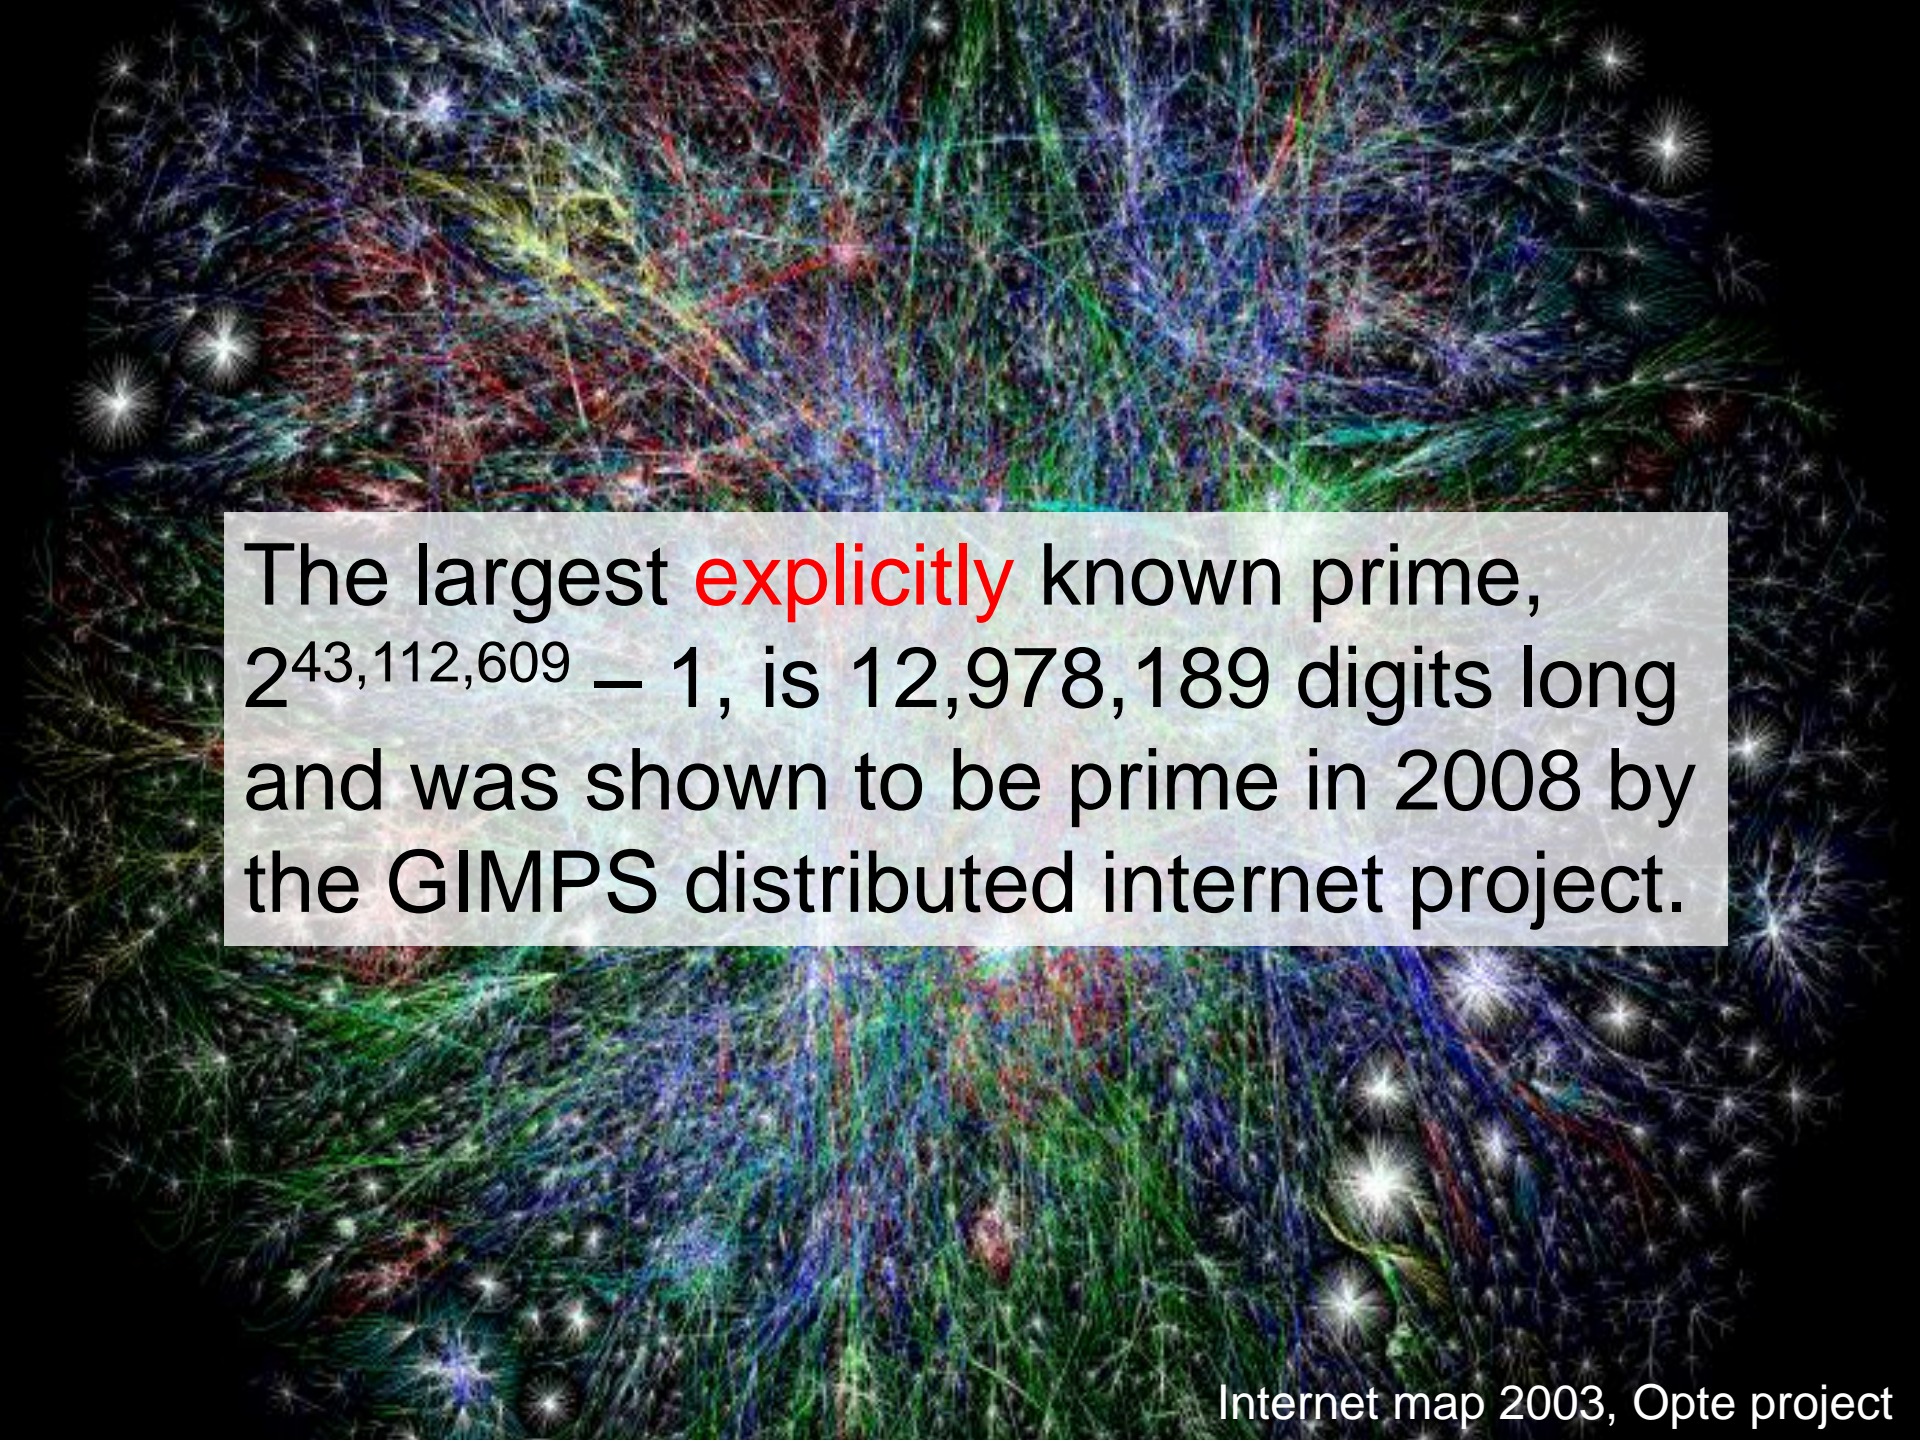

Public

In fact, many modern cryptographic protocols - such as the **RSA algorithm** - rely crucially on the inability to factor large numbers (200+ digits) in a practical amount of time.

Public key encryption

Similarly, **Euclid's theorem** tells us **in principle** that there are arbitrarily large primes out there, but does not give a recipe to find them.

The largest **explicitly** known prime, $2^{43,112,609} - 1$, is 12,978,189 digits long and was shown to be prime in 2008 by the GIMPS distributed internet project.

(3, 5), (5, 7), (11, 13), (17, 19), (29, 31), (41, 43), (59, 61), (71, 73), (101, 103), (107, 109), (137, 139), (149, 151), (179, 181), (191, 193), (197, 199), (227, 229), (239, 241), (269, 271), (281, 283), (311, 313), (347, 349), (419, 421), (431, 433), (461, 463), (521, 523), (569, 571), (599, 601), (617, 619), (641, 643), (659, 661), (809, 811), (821, 823), (827, 829), (857, 859),

Indeed, the prime numbers seem to be so “randomly” distributed that it is often difficult to establish what patterns exist within them. For instance, the following conjecture remains unproven:

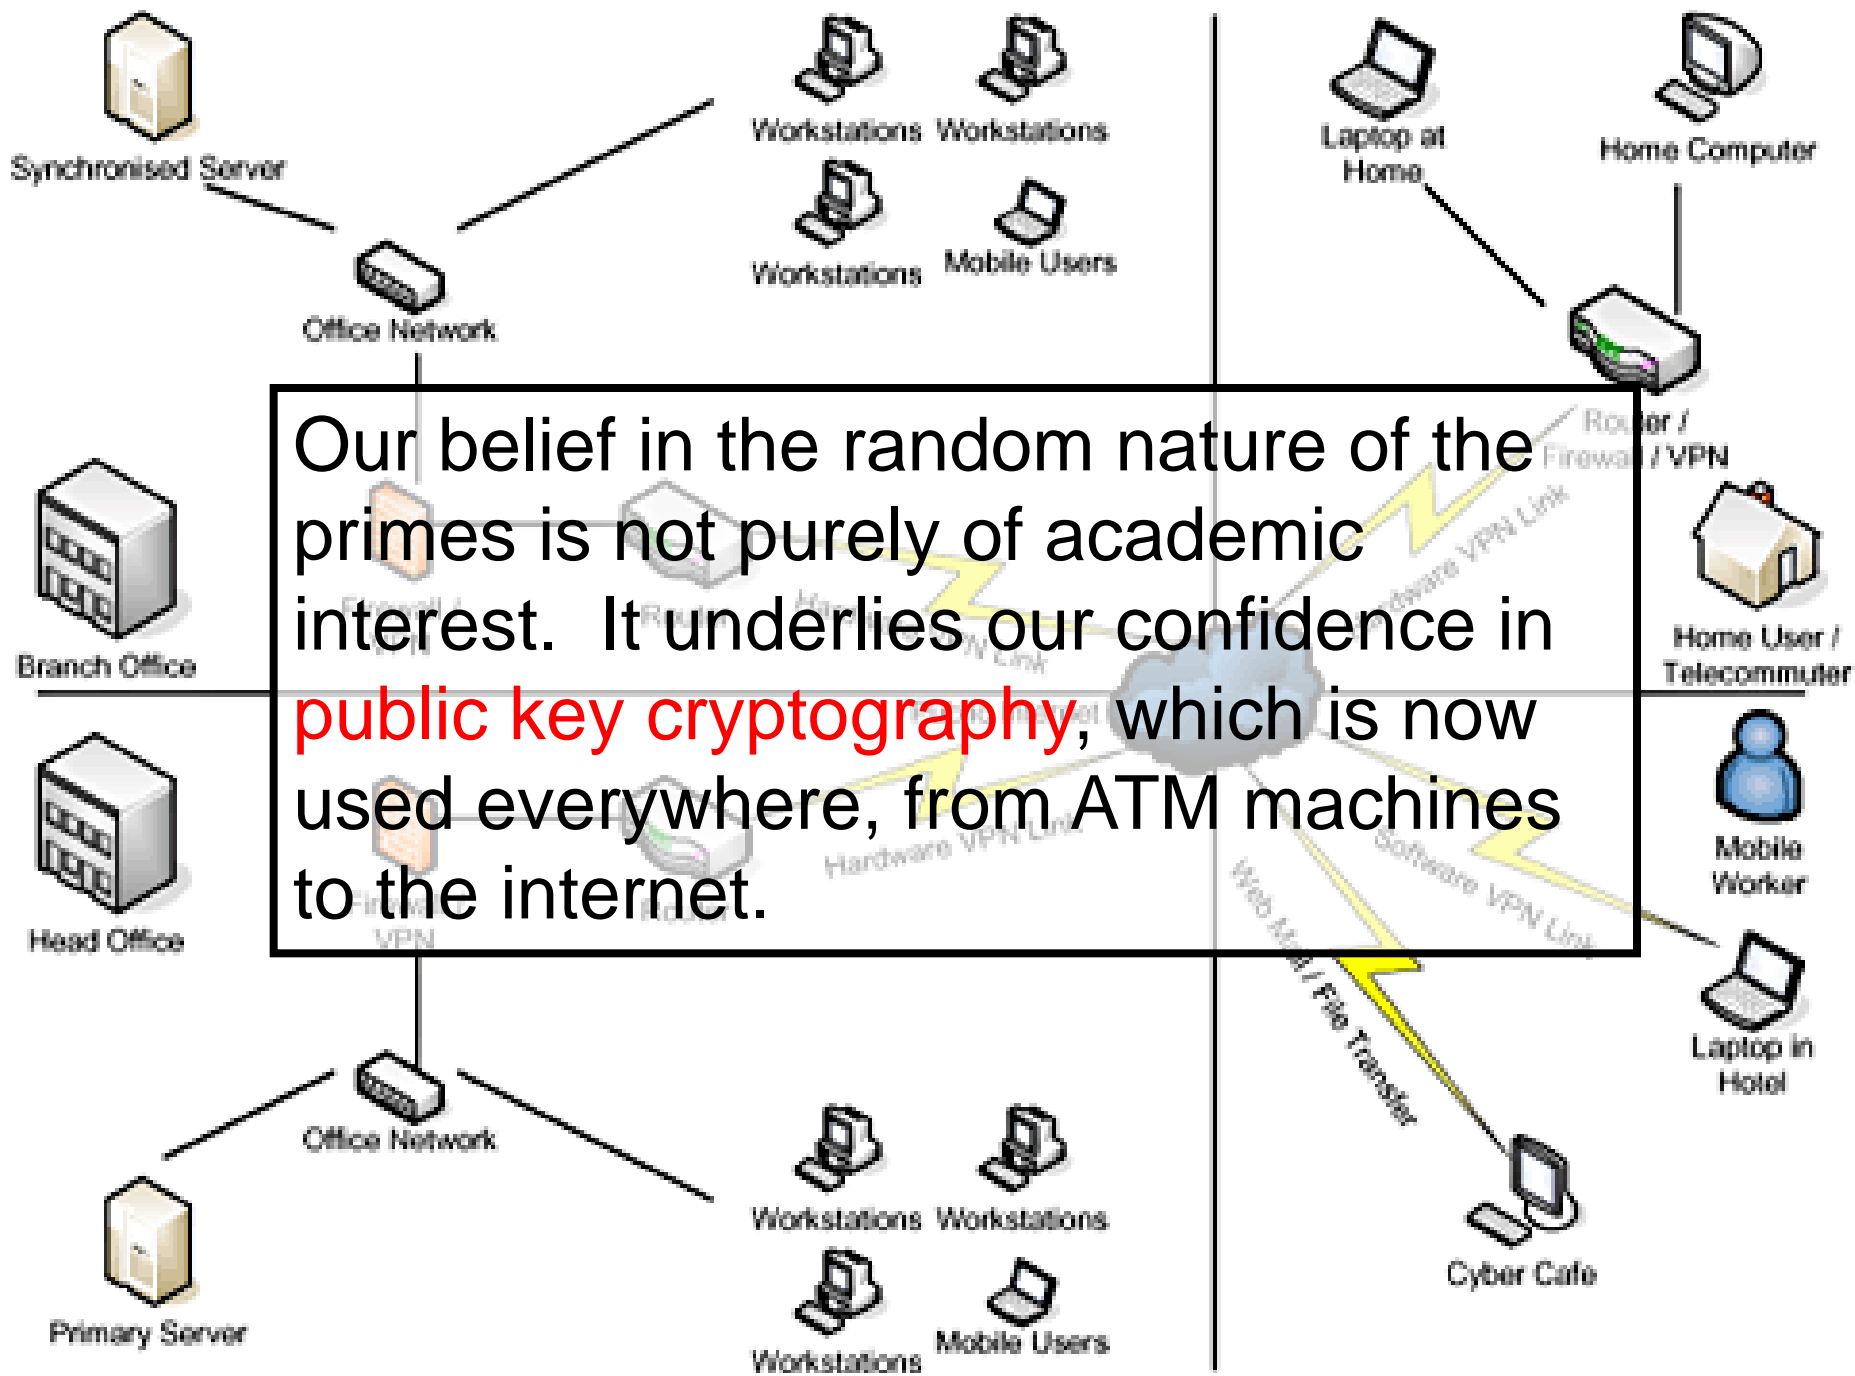

Twin prime conjecture (? ~300 BCE ?): There exist infinitely many pairs $p, p+2$ of primes which differ by exactly 2. (1487, 1489), (1607, 1609), ...

..., $(2,003,663,613 \times 2^{195,000} \pm 1)$ [Vautier, 2007], ¿...?

“God may not play dice with the universe, but something strange is going on with the prime numbers”.

(Paul Erdős, 1913-1996)

Our belief in the random nature of the primes is not purely of academic interest. It underlies our confidence in **public key cryptography**, which is now used everywhere, from ATM machines to the internet.

Public key cryptography – a physical analogy

- Alice wants to send a box g of valuables by post to a distant friend Bob.
- But Alice worries that someone may intercept the box and take the contents.
- She could lock the box, but how would she send the key over to Bob without risking that the key is intercepted (and copied)?

Solution: a three-pass protocol

Alice locks the box g with a padlock a .
She then sends the locked box g^a to
Bob, keeping the key.

Solution: a three-pass protocol

Bob cannot unlock the box... but he can put his own padlock b on the box. He then sends the doubly locked box g^{ab} back to Alice.

Solution: a three-pass protocol

Alice can't unlock Bob's padlock... but she can unlock her own! She then sends the singly locked box g^b back to Bob.

Solution: a three-pass protocol

Bob then unlocks his own lock and opens the box.

Solution: a three-pass protocol

An eavesdropper would see the locked boxes g^a , g^{ab} , g^b ... but never the unlocked box g .

The same method works for sending a digital message g , and is known as the **Massey-Omura cryptosystem**:

1. Alice and Bob agree (publicly) on a large prime p .
2. Alice “locks” g by raising it to the power a for some secretly chosen a . She then sends $g^a \bmod p$ to Bob.
3. Bob “locks” the message by raising to his own power b , and sends $g^{ab} \bmod p$ back to Alice.
4. Alice takes an a^{th} root to obtain $g^b \bmod p$, which she sends back to Bob.
5. Bob takes a b^{th} root to recover g .

EXPSPACE

EXPTIME

It is believed, but not yet proven, that these algorithms are secure against eavesdropping. (This conjecture is related to the infamous **P=NP problem**, to which the Clay Mathematics Institute has offered a US\$1,000,000 prize.)

BPP

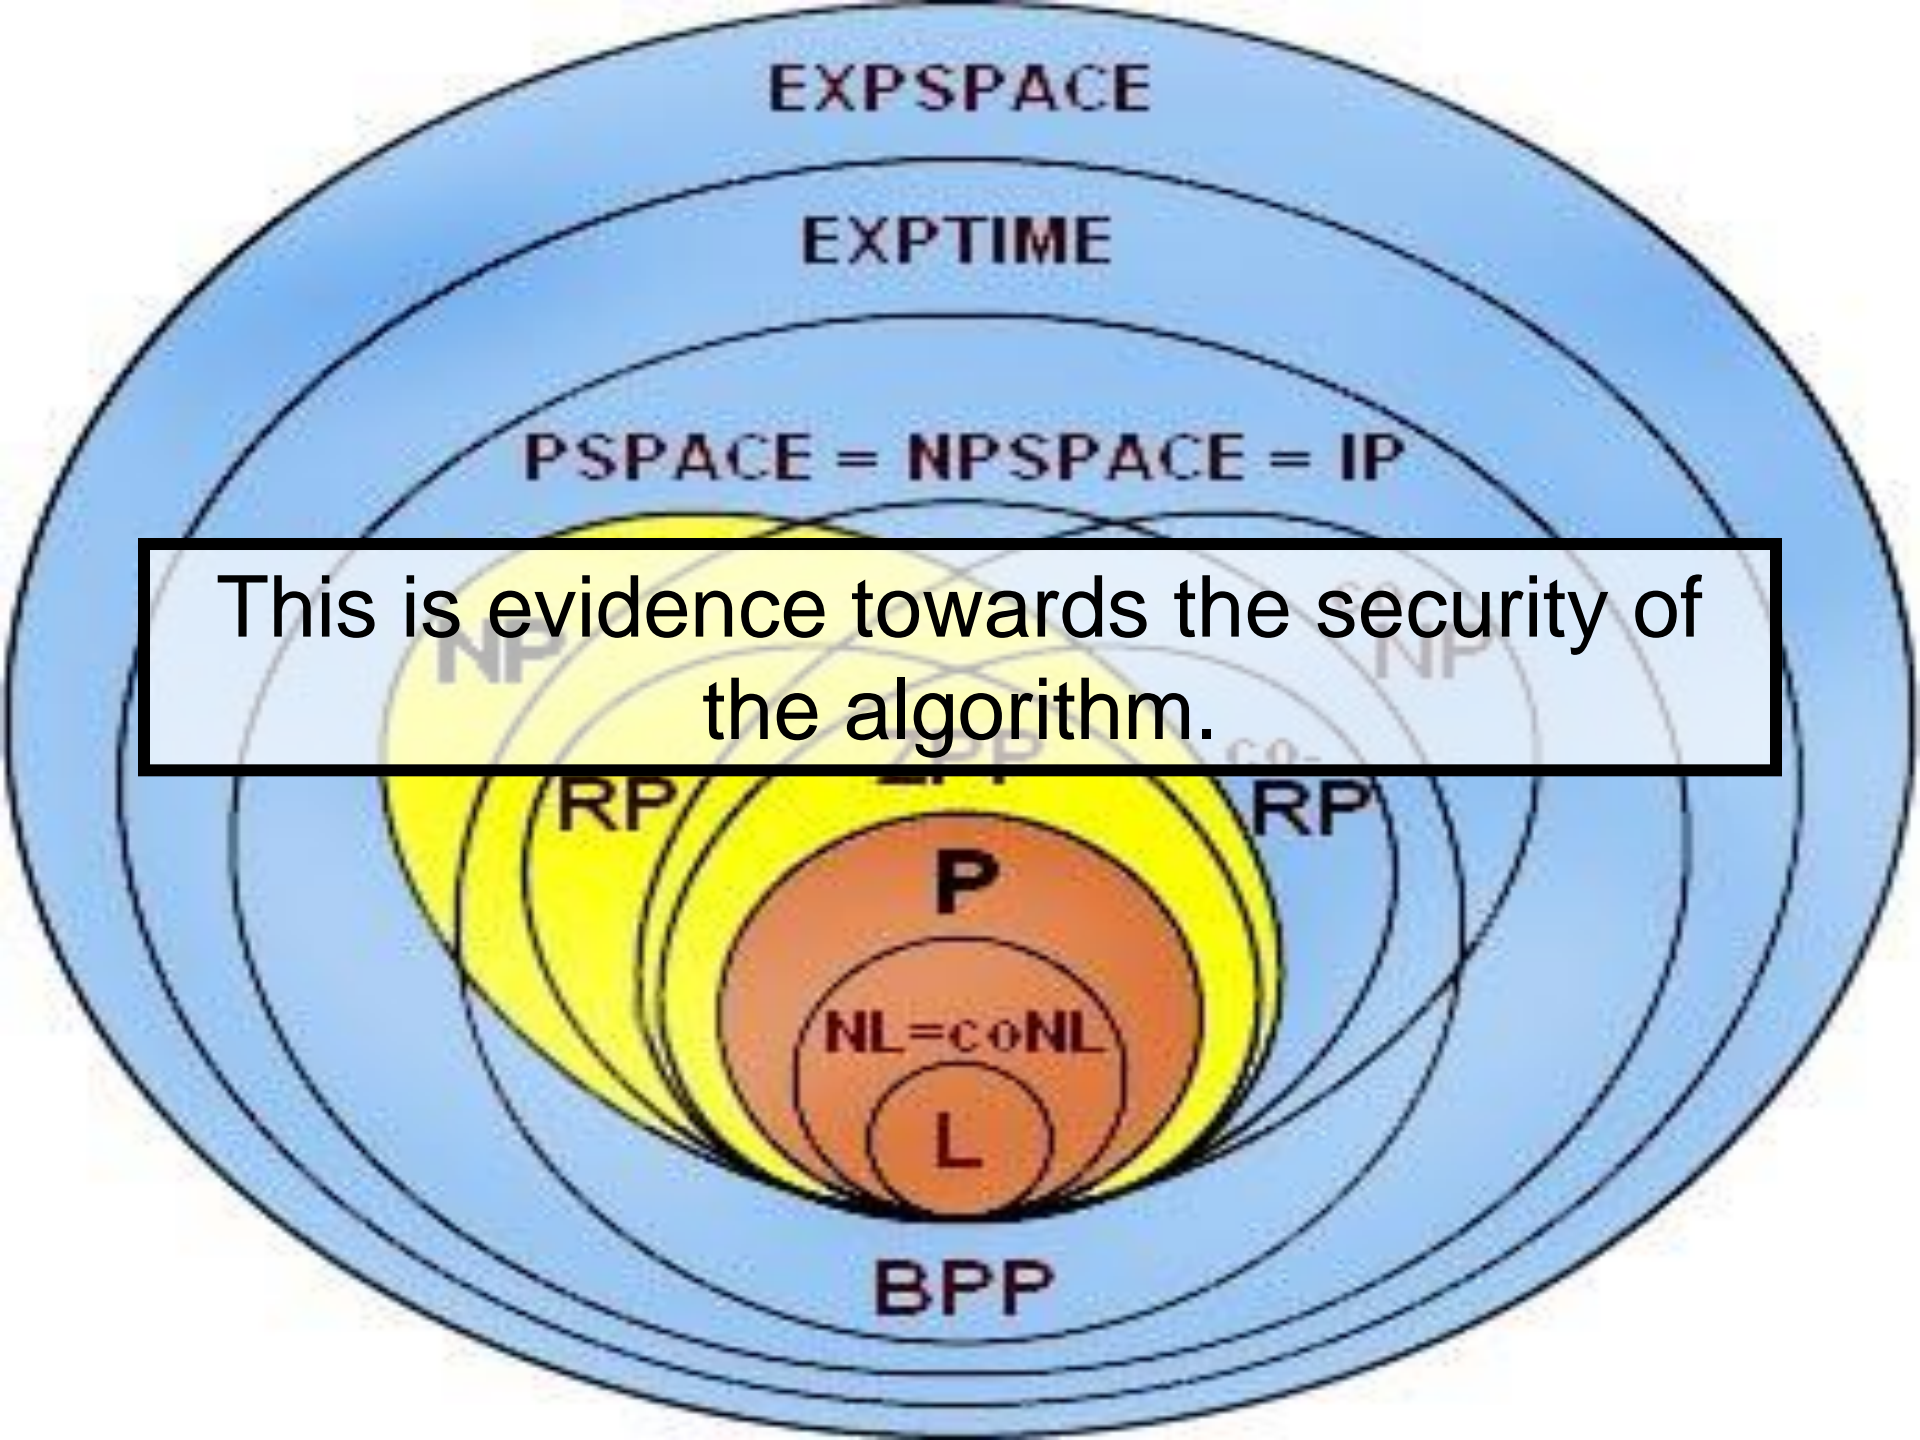

L

EXPSPACE

EXPTIME

However, it was recently shown that the data that an eavesdropper intercepts via this protocol (i.e. g^a , g^b , $g^{ab} \bmod p$) is **uniformly distributed**, which means that the most significant digits look like random noise (Bourgain, 2004).

BPP

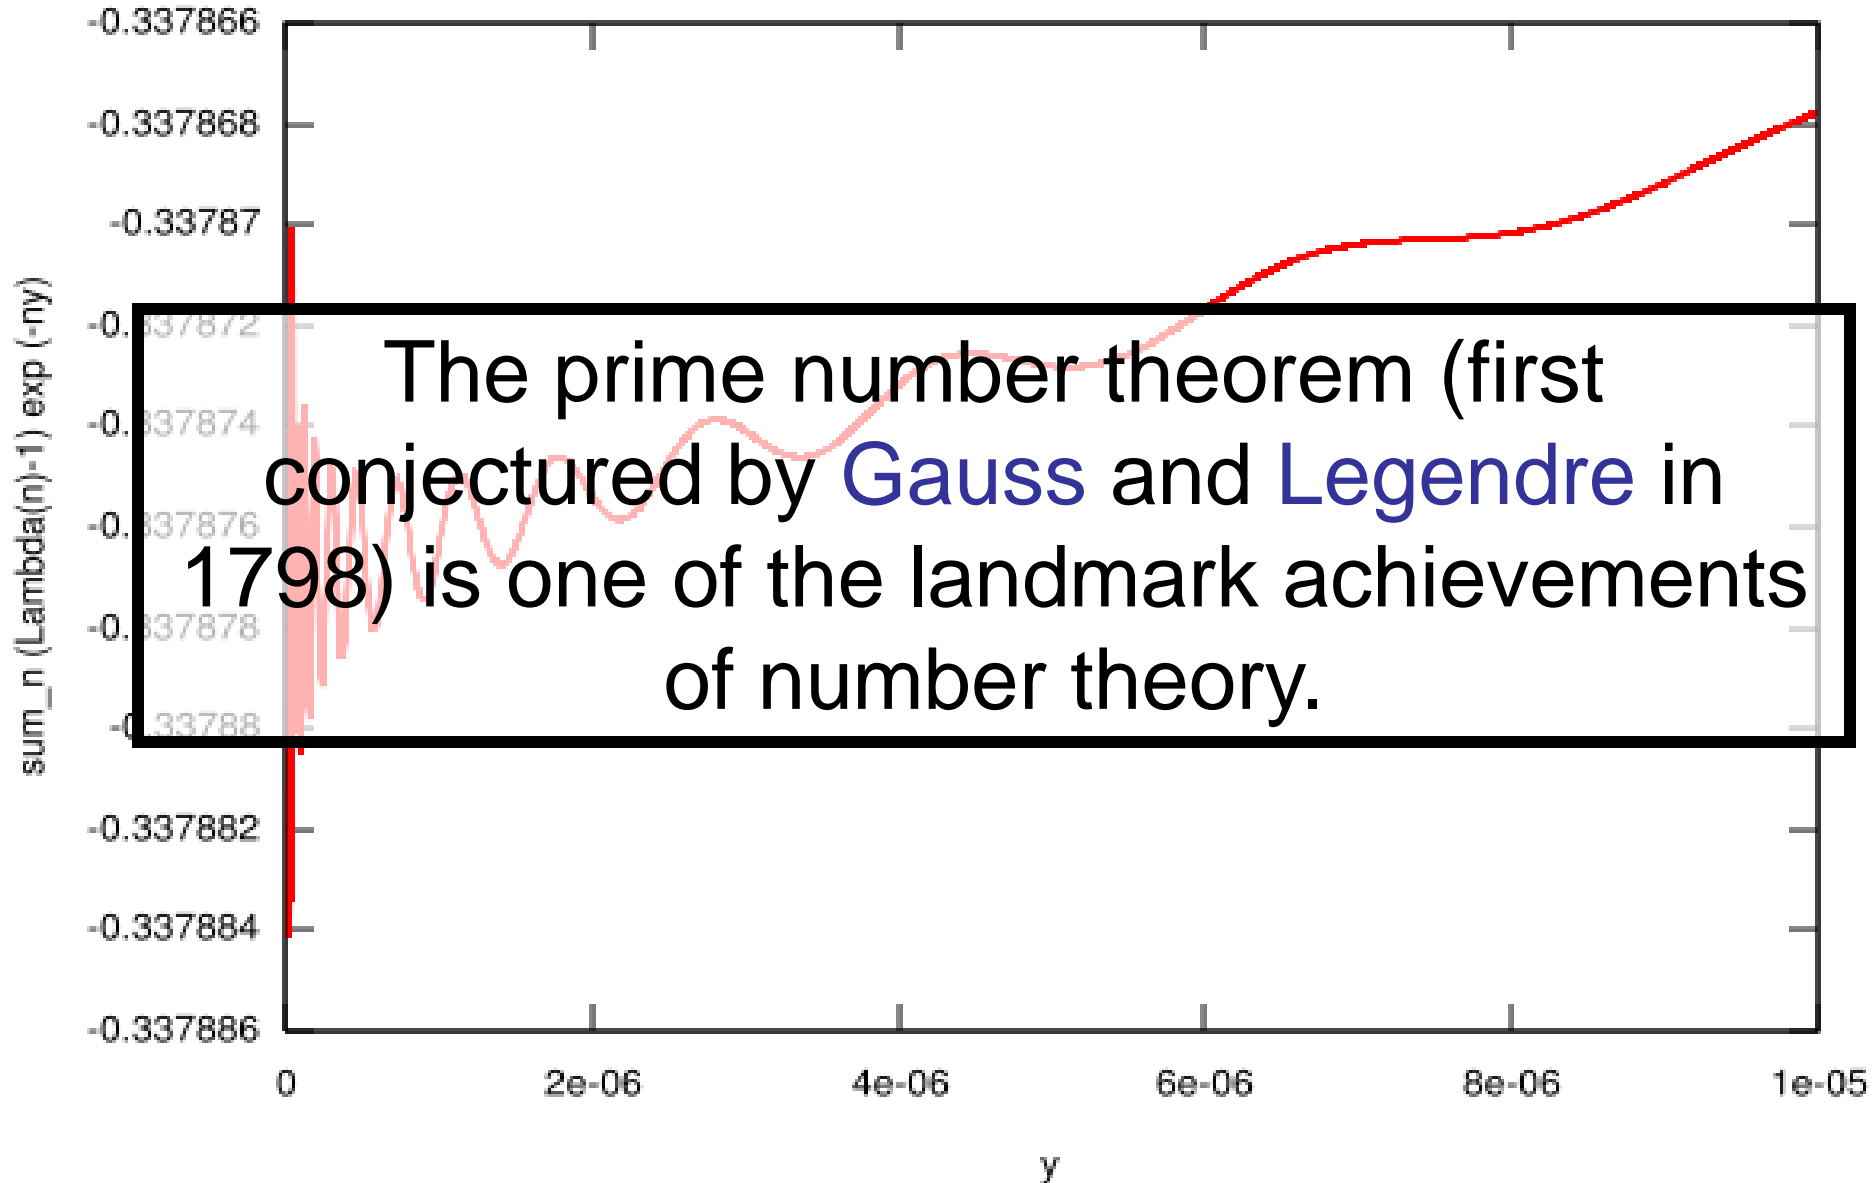

This is evidence towards the security of the algorithm.

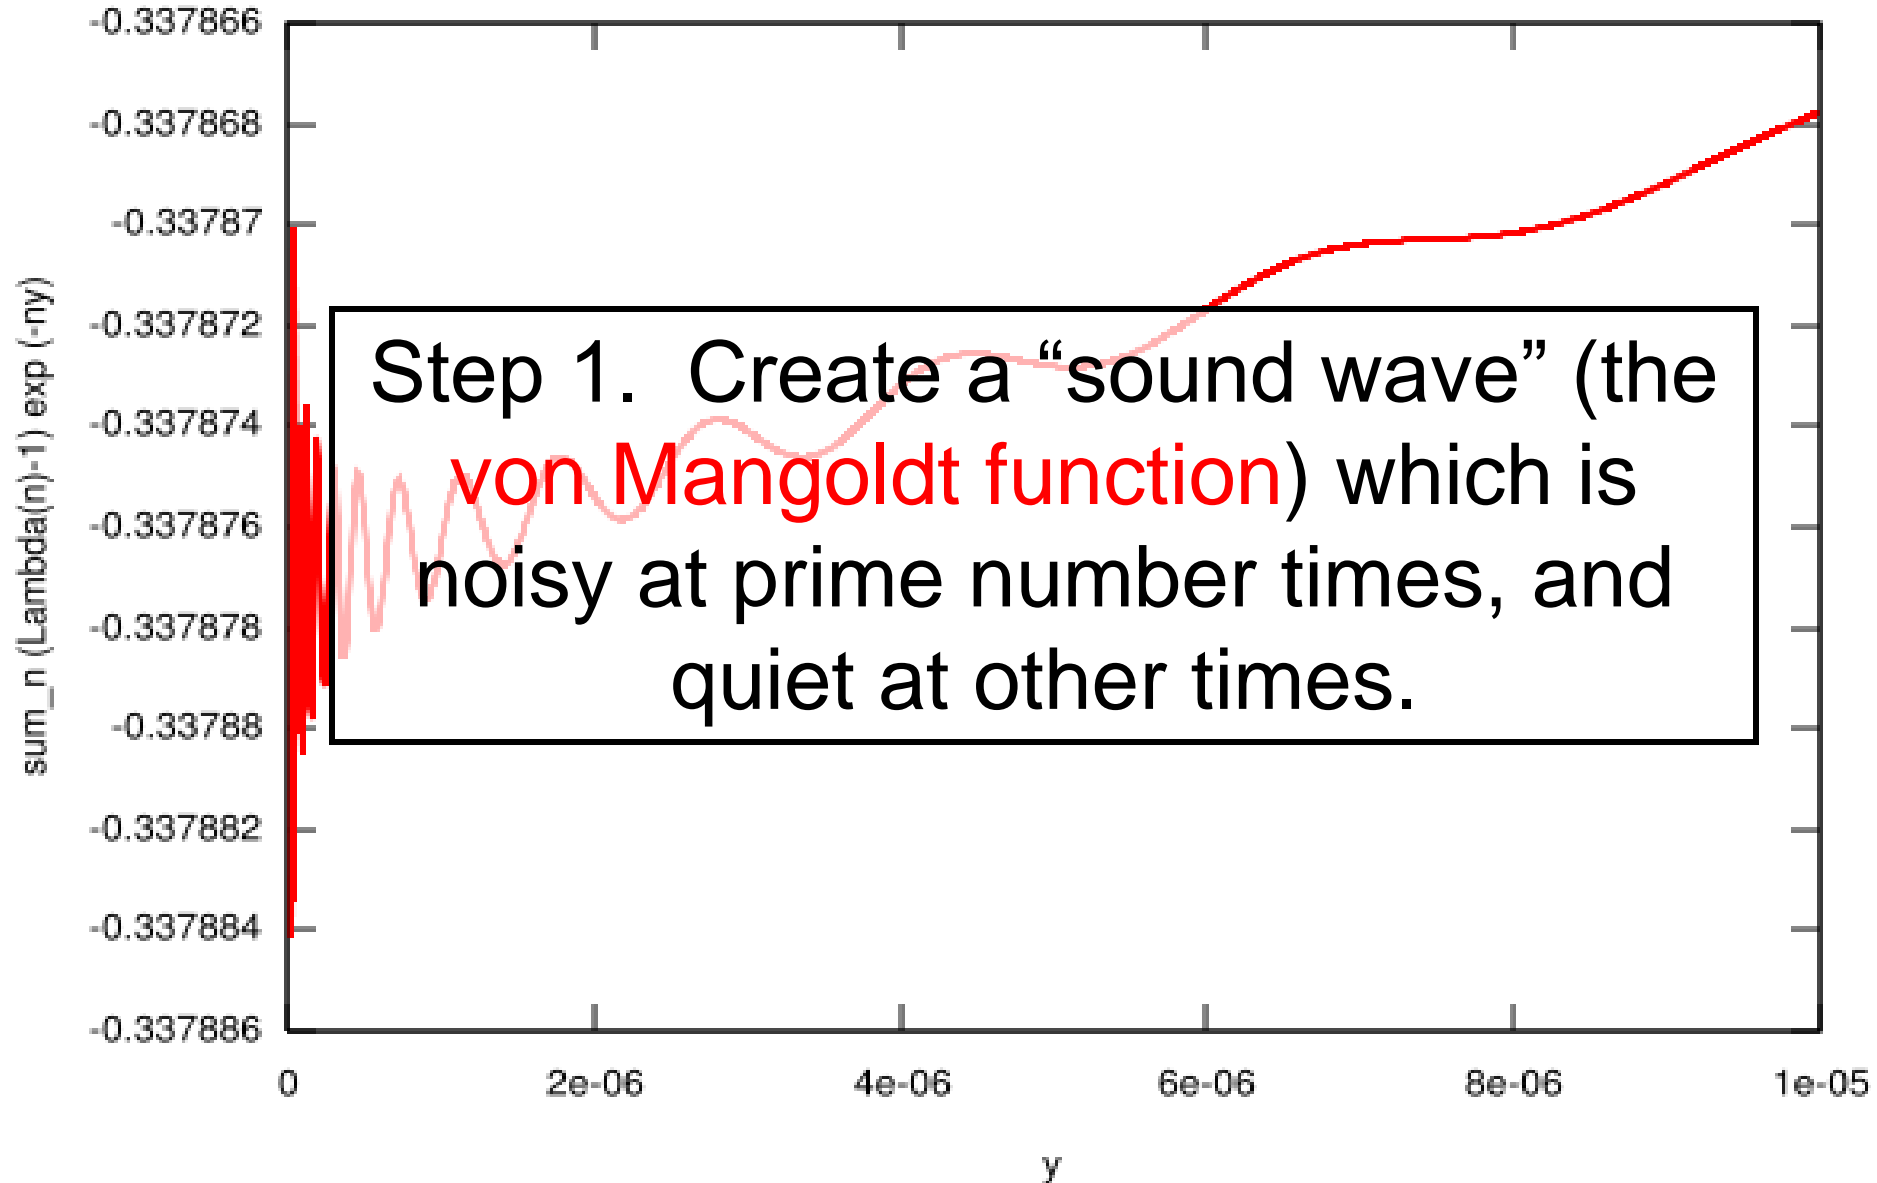

von Mangoldt Exponential Series

von Mangoldt Exponential Series

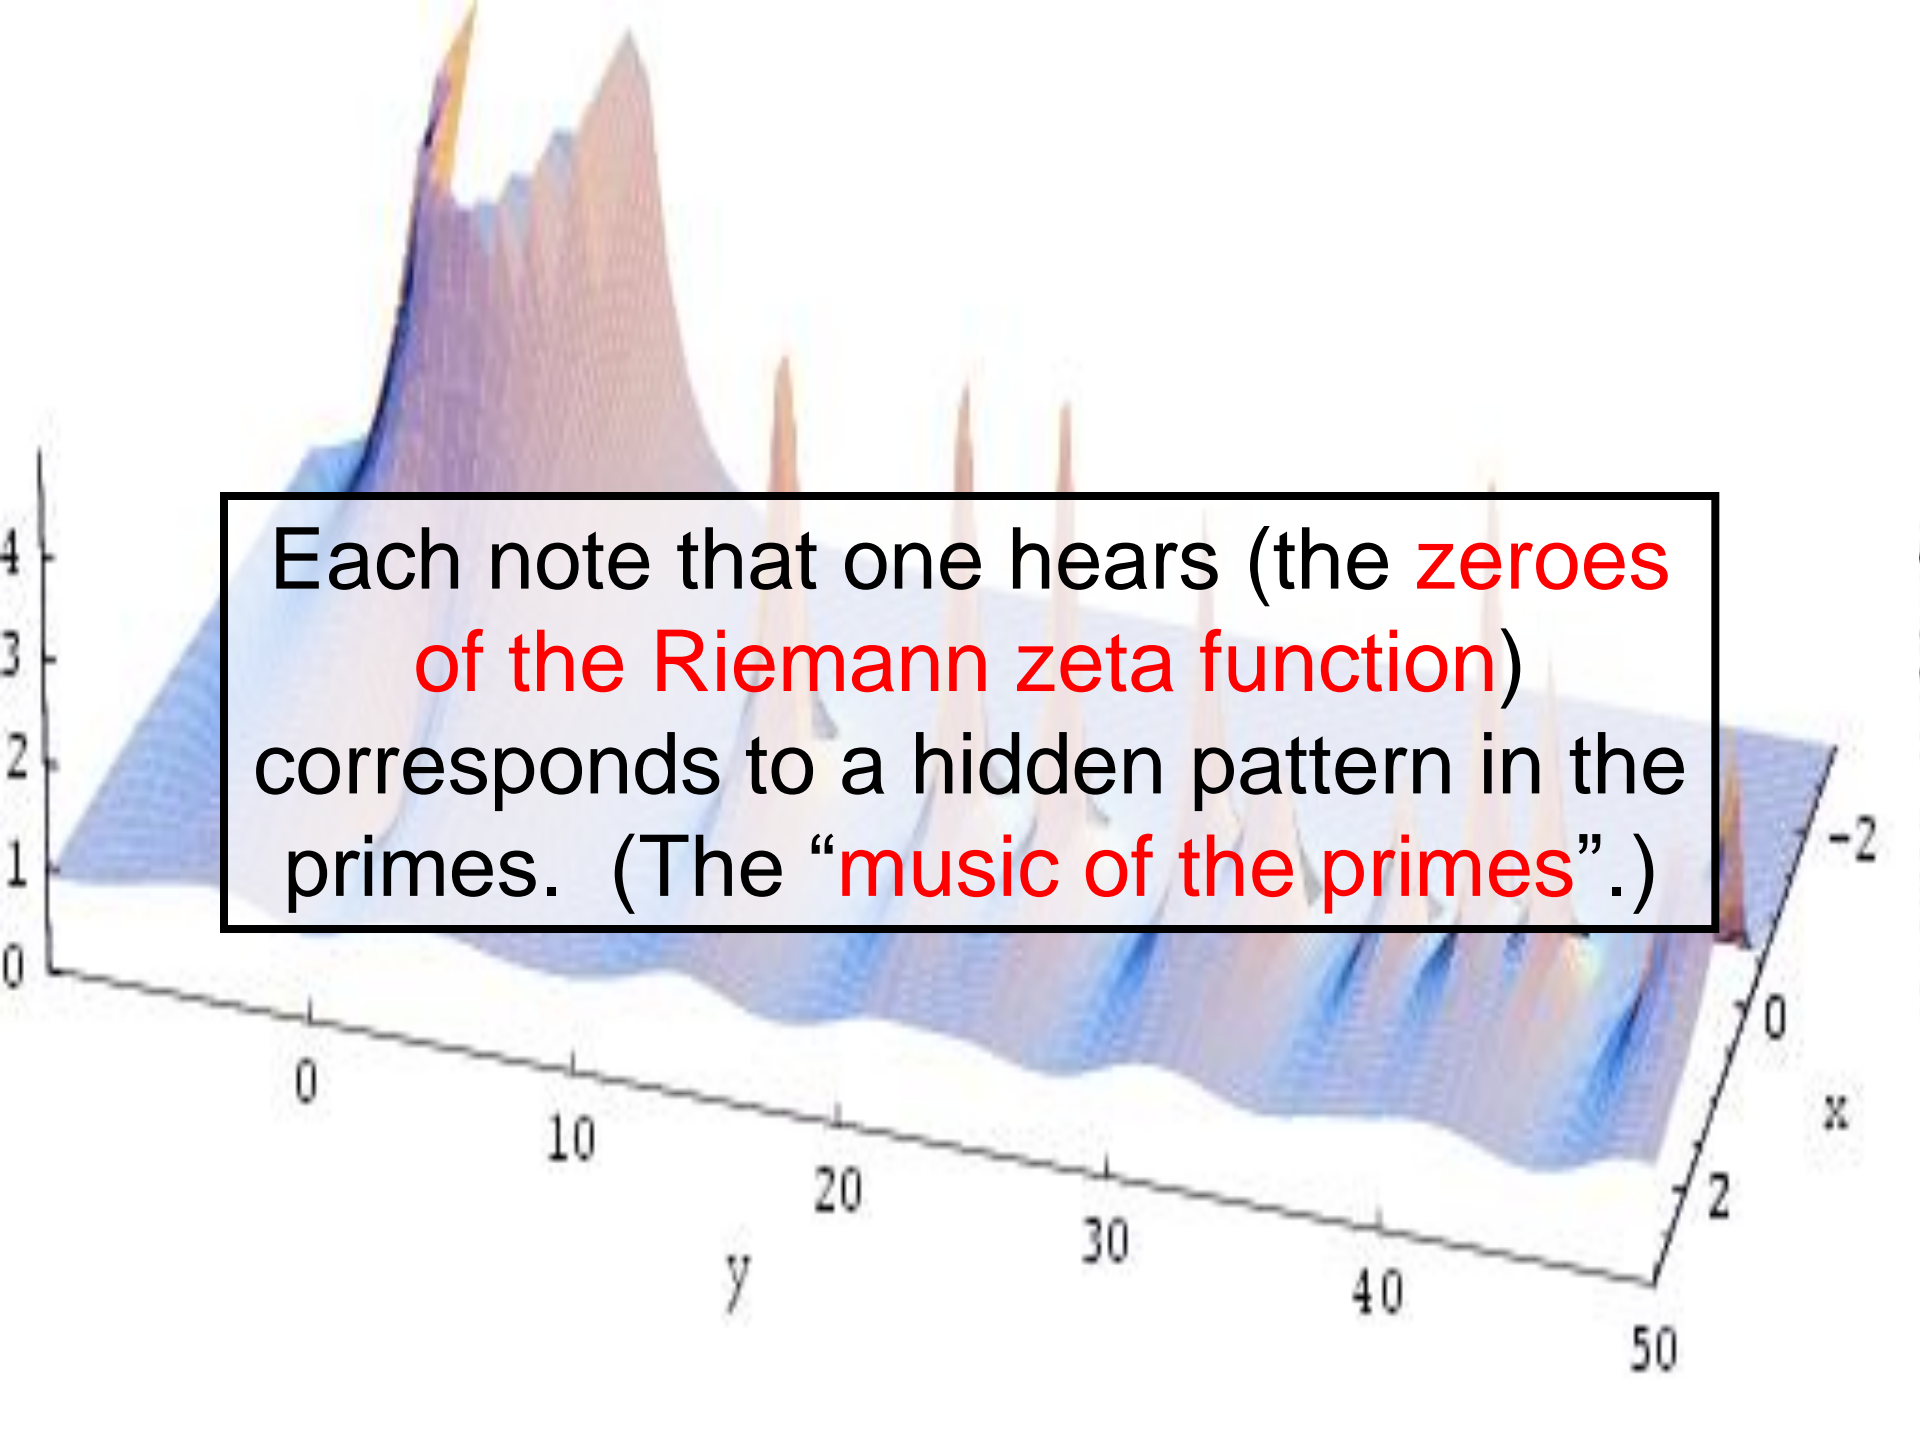

von Mangoldt Exponential Series

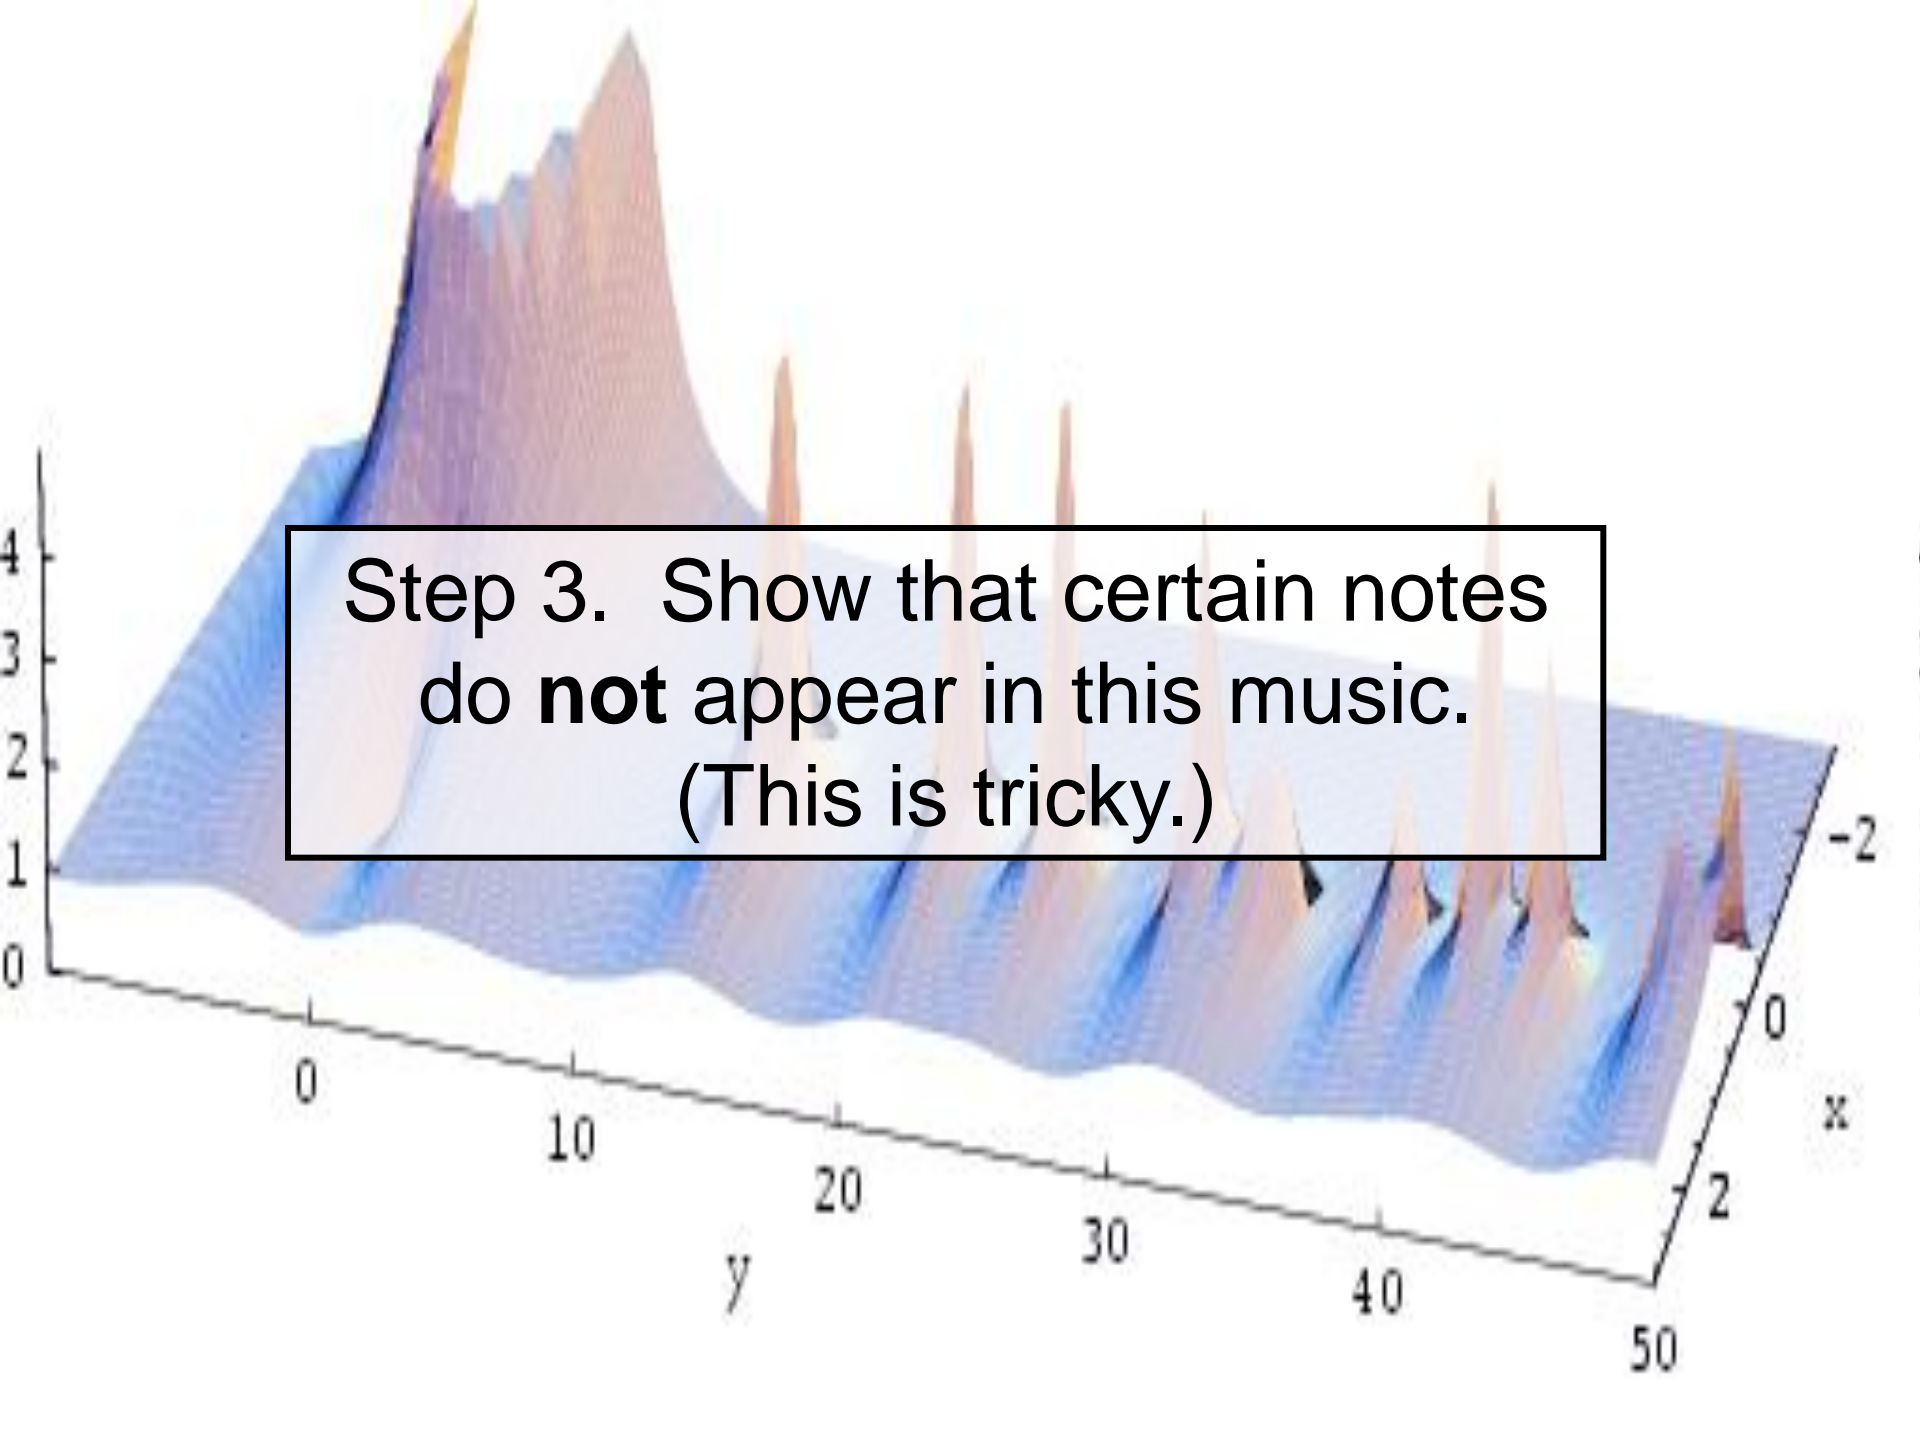

von Mangoldt Exponential Series

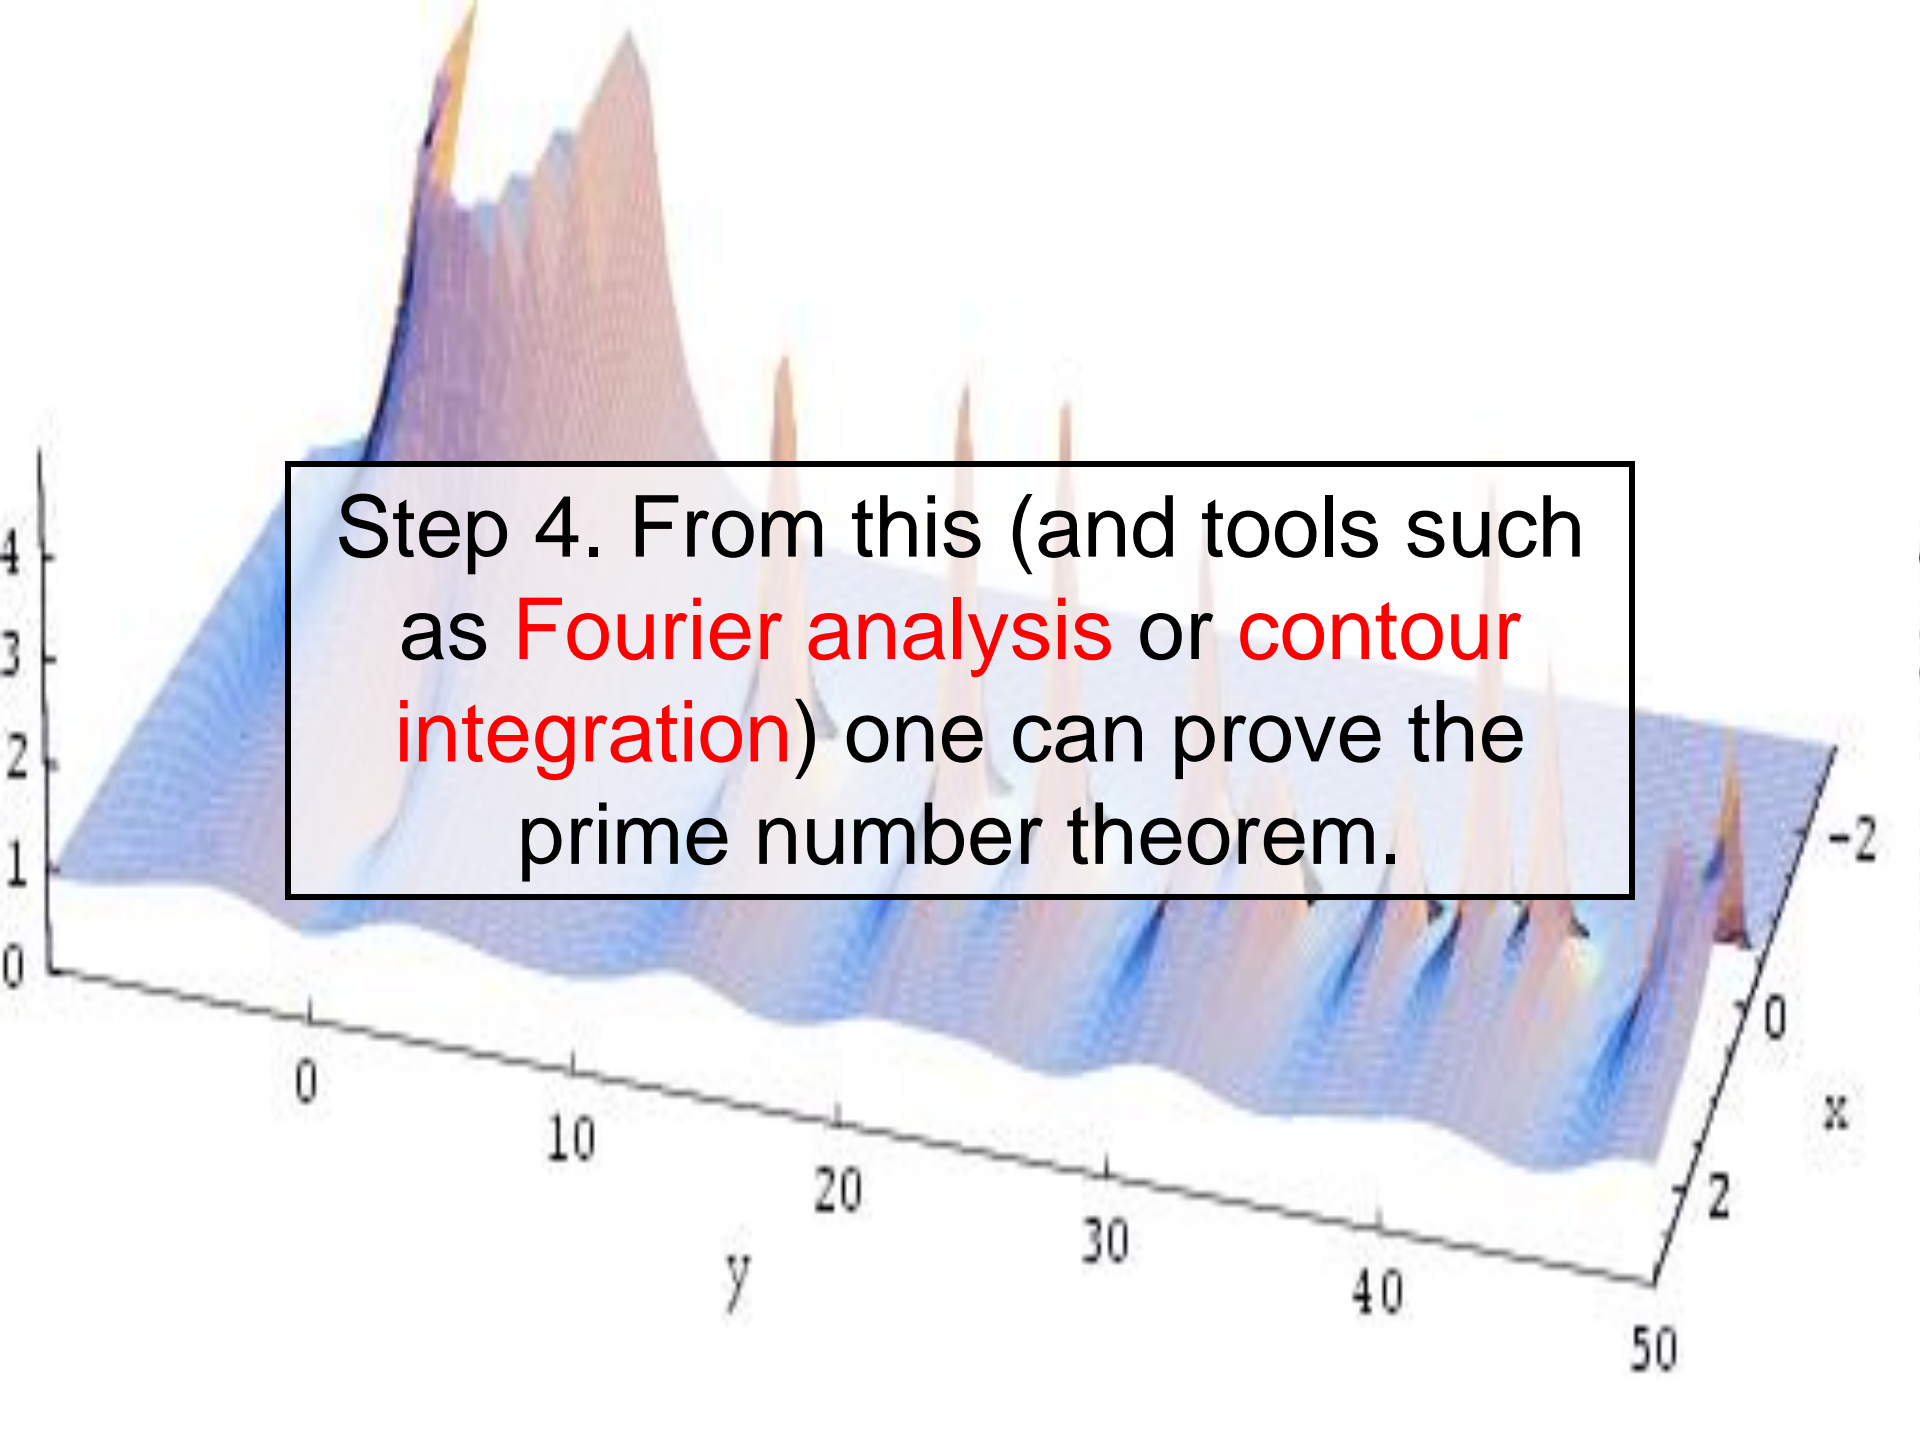

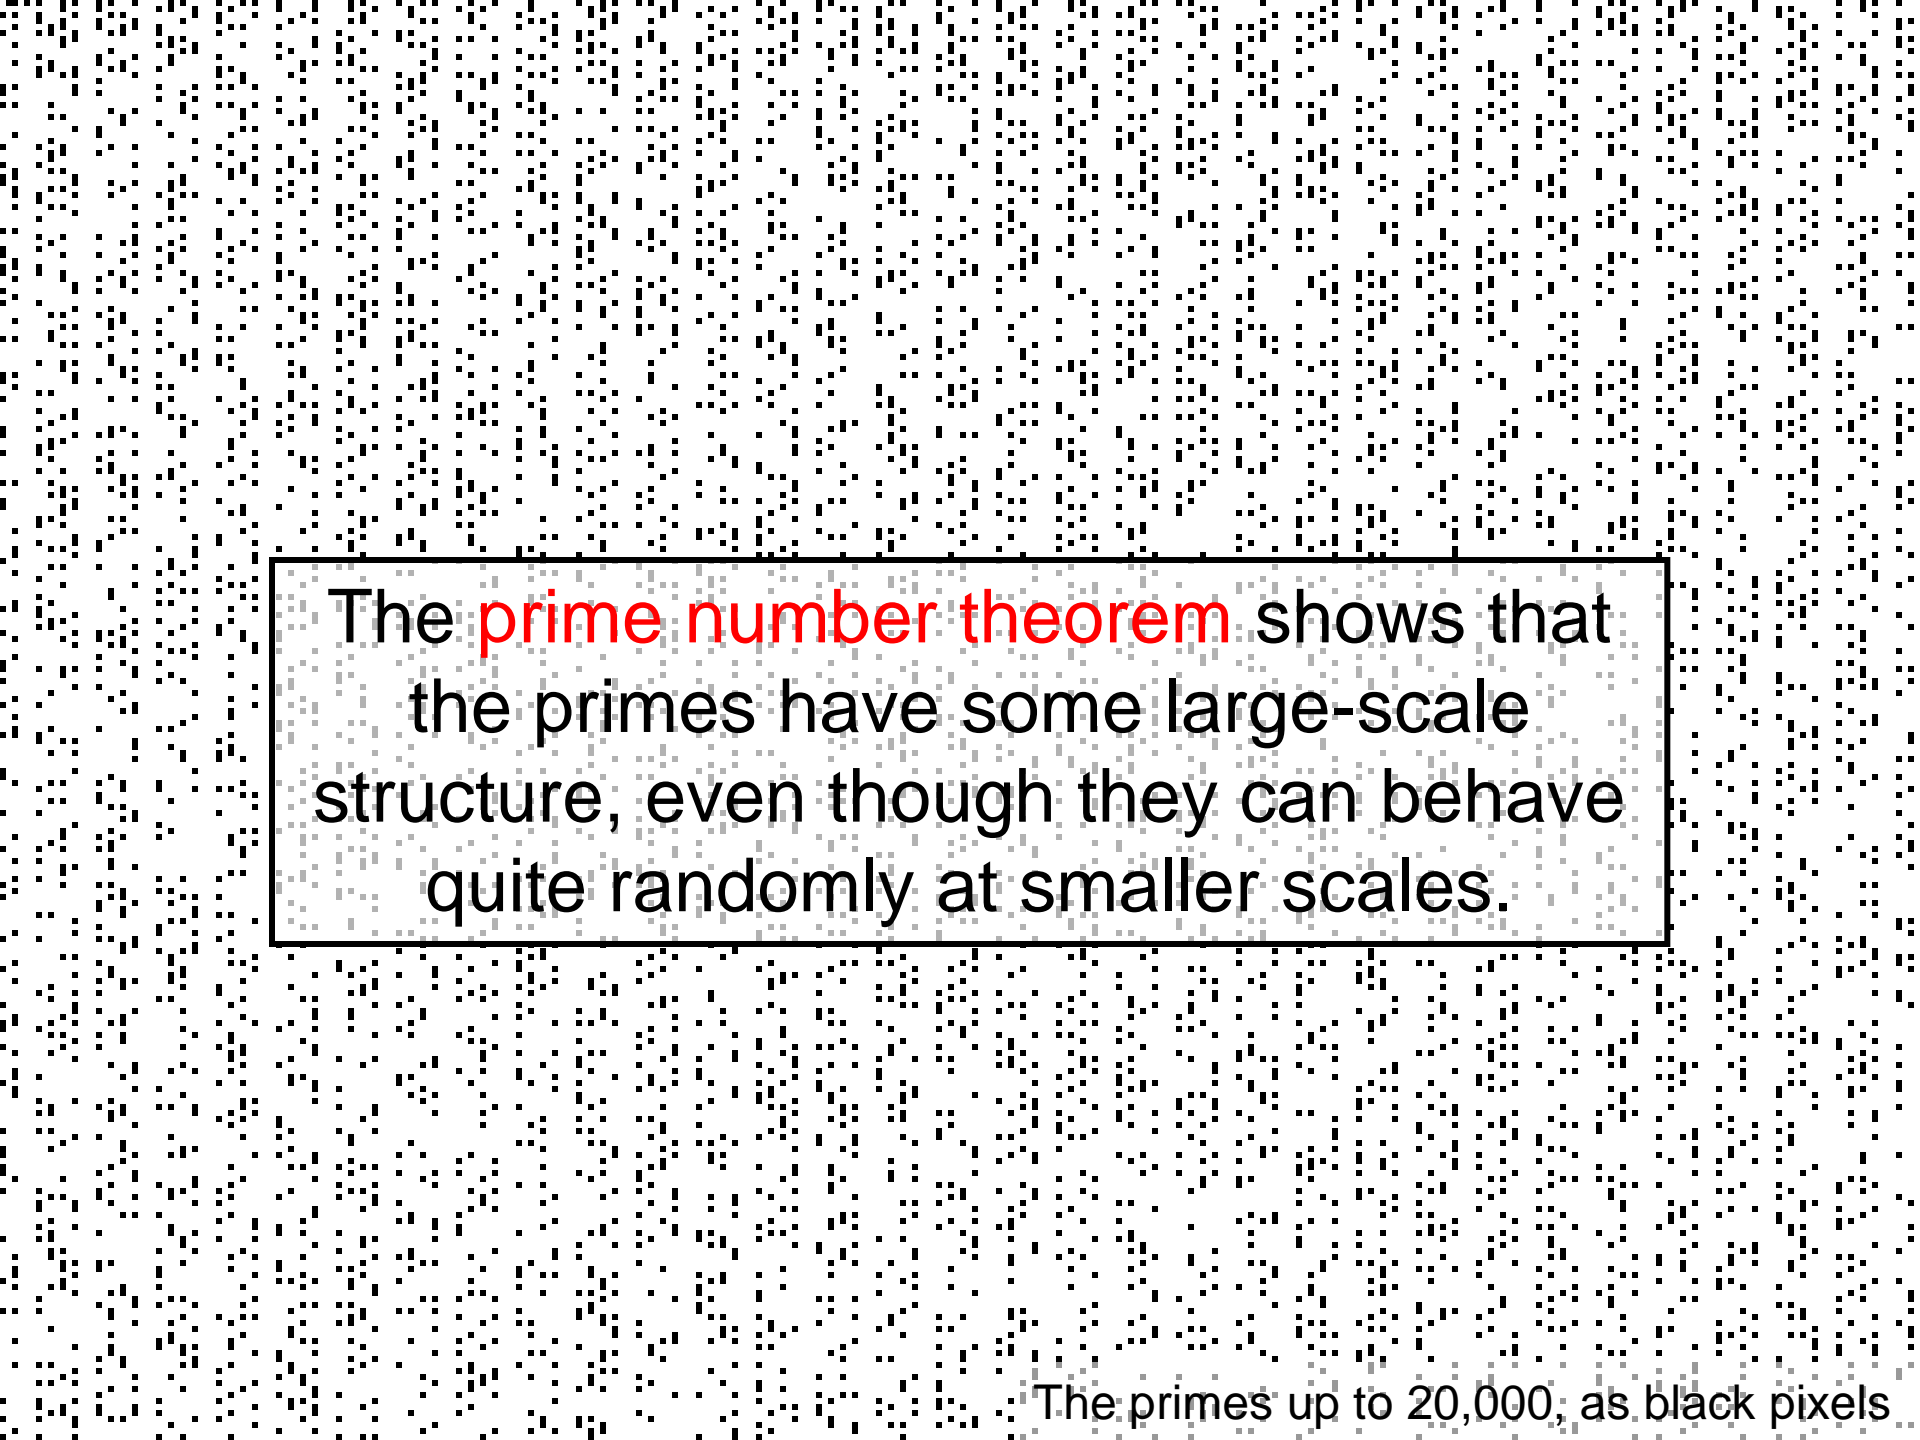

Each note that one hears (the **zeroes of the Riemann zeta function**) corresponds to a hidden pattern in the primes. (The “**music of the primes**”.)

Step 3. Show that certain notes
do **not** appear in this music.
(This is tricky.)

Step 4. From this (and tools such as **Fourier analysis** or **contour integration**) one can prove the prime number theorem.

The **prime number theorem** shows that the primes have some large-scale structure, even though they can behave quite randomly at smaller scales.

The primes up to 20,000, as black pixels

On the other hand, the primes also have some local structure. For instance,

- They are all odd (with one exception);
- They are all adjacent to a multiple of six (with two exceptions);
- Their last digit is always 1, 3, 7, or 9 (with two exceptions).

It is possible to use this large-scale structure, local structure, and small-scale randomness to prove some non-trivial results. For instance:

The primes up to 20,000, as black pixels

Vinogradov's theorem (1937):
every sufficiently large odd
number n can be written as
the sum of three primes.

In 1742, **Christian Goldbach** conjectured
that in fact **every** odd number n greater
than 5 should be the sum of three
primes. This is currently only known for
 n larger than 10^{1346} (**Liu-Wang**, 2002)
and less than 10^{20} (**Saouter**, 1998).

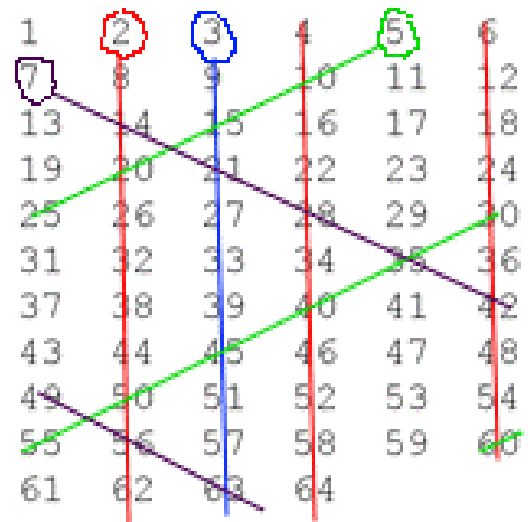

Chen's theorem (1966).

There exists infinitely many pairs $p, p+2$, where p is a prime, and $p+2$ is either a prime or the product of two primes.

This is the best partial result we have on the **twin prime conjecture**. The proof uses an advanced form of **sieve theory**.

The Sieve of Eratosthenes, $n=1$ to 64

3,5,7

5,11,17,23

5,11,17,23,29

Green-Tao theorem (2004). The prime numbers contain arbitrarily long arithmetic progressions.

199, 409, 619, 829, 1039, 1249, 1459, 1669, 1879, 2089

110437, 124297, 138157, 152017, 165877, 179737, ..., 249037

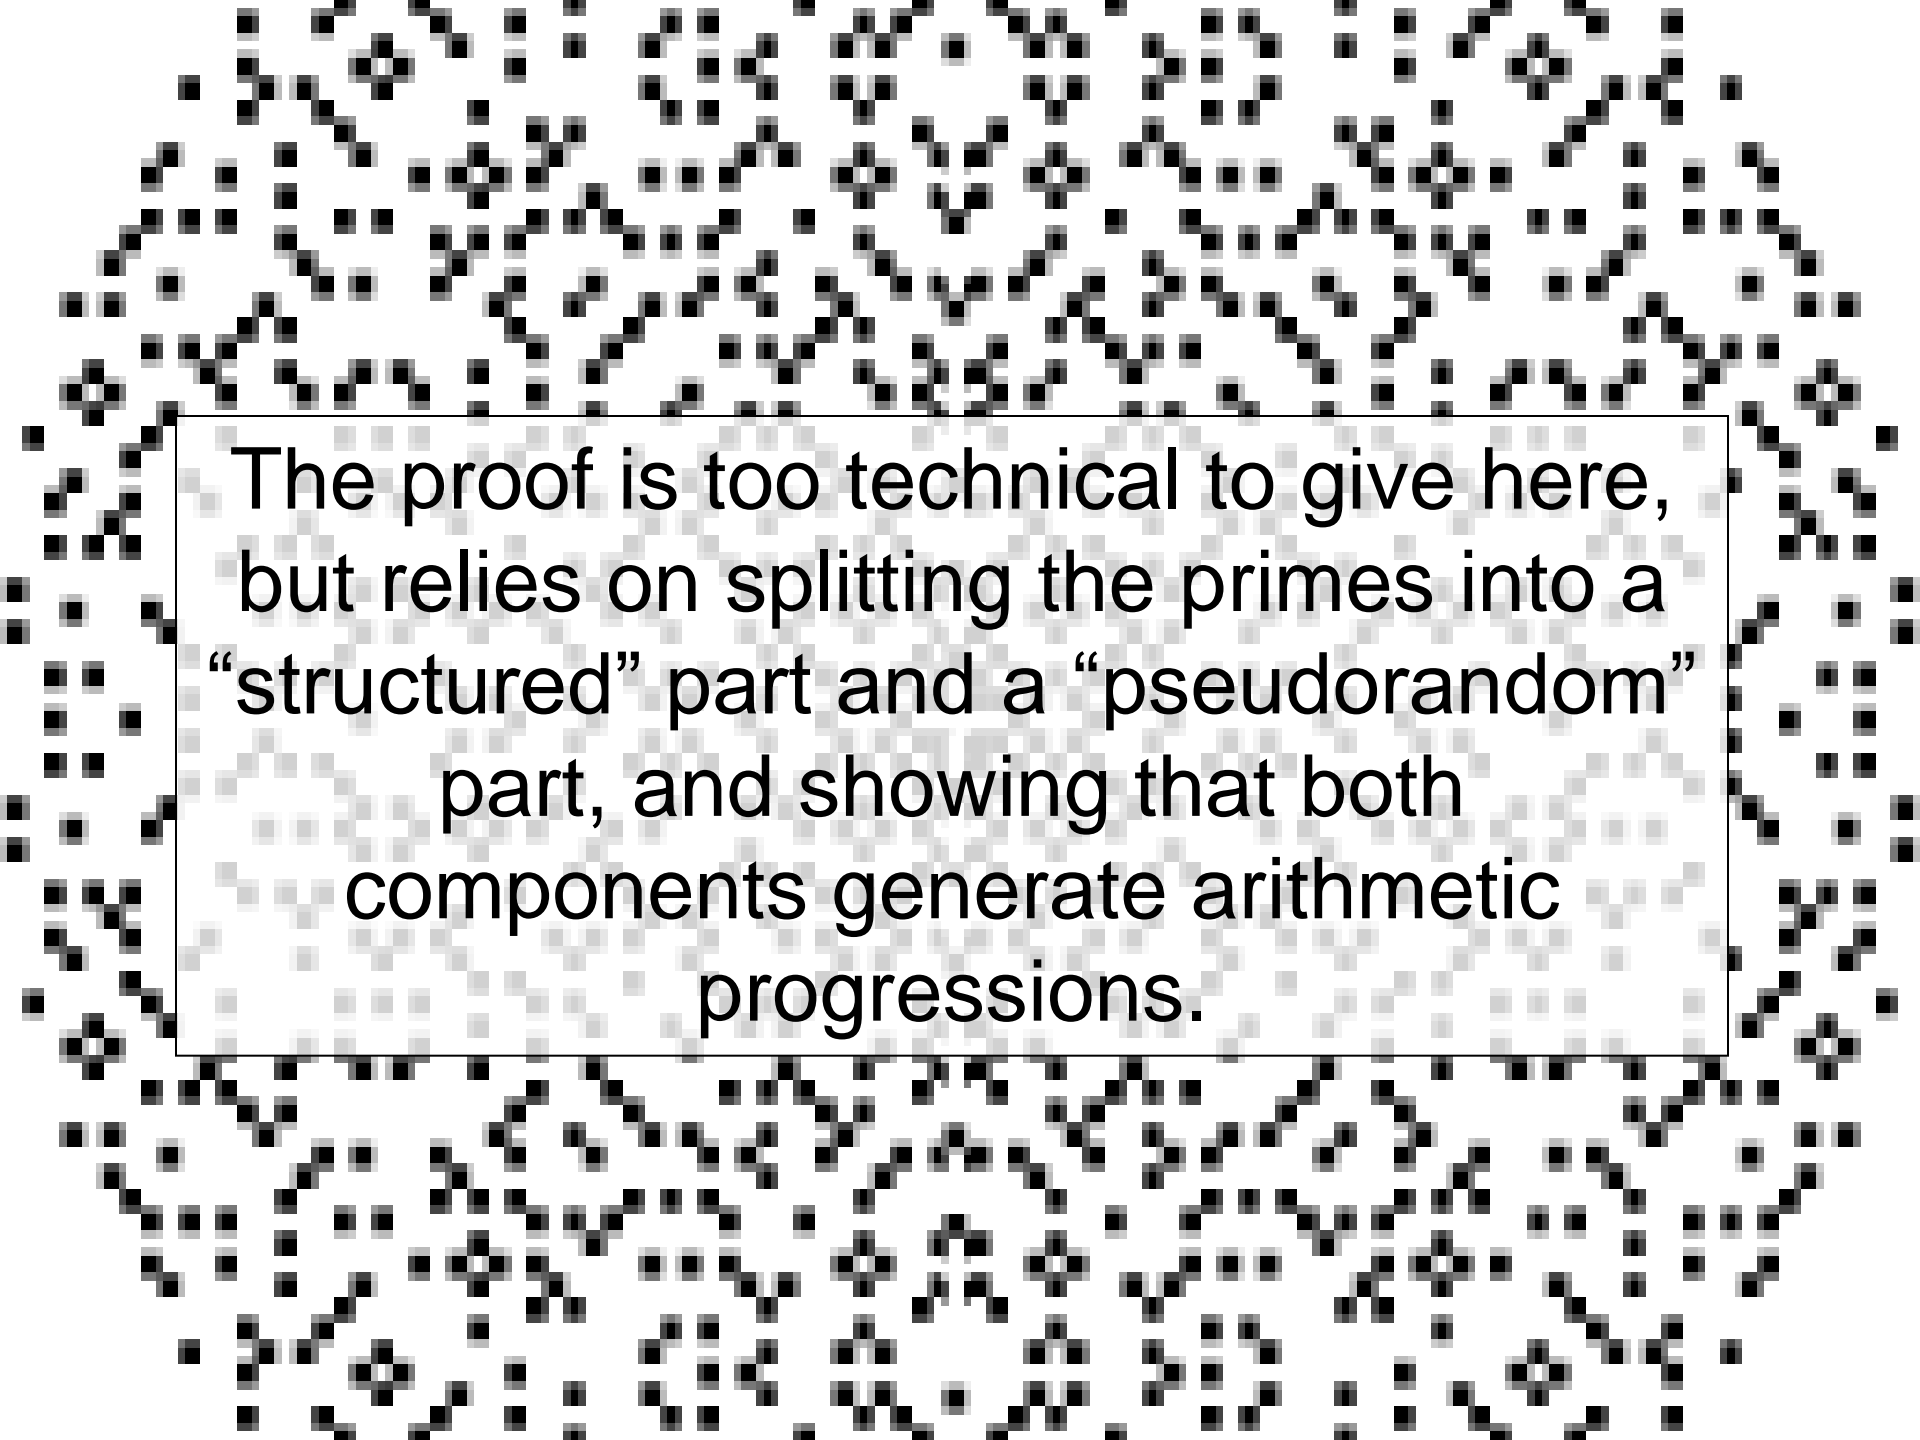

...

$56,211,383,760,397 + 44,546,738,095,860n$, $n=0,\dots,22$ (Frind et al., 2004)

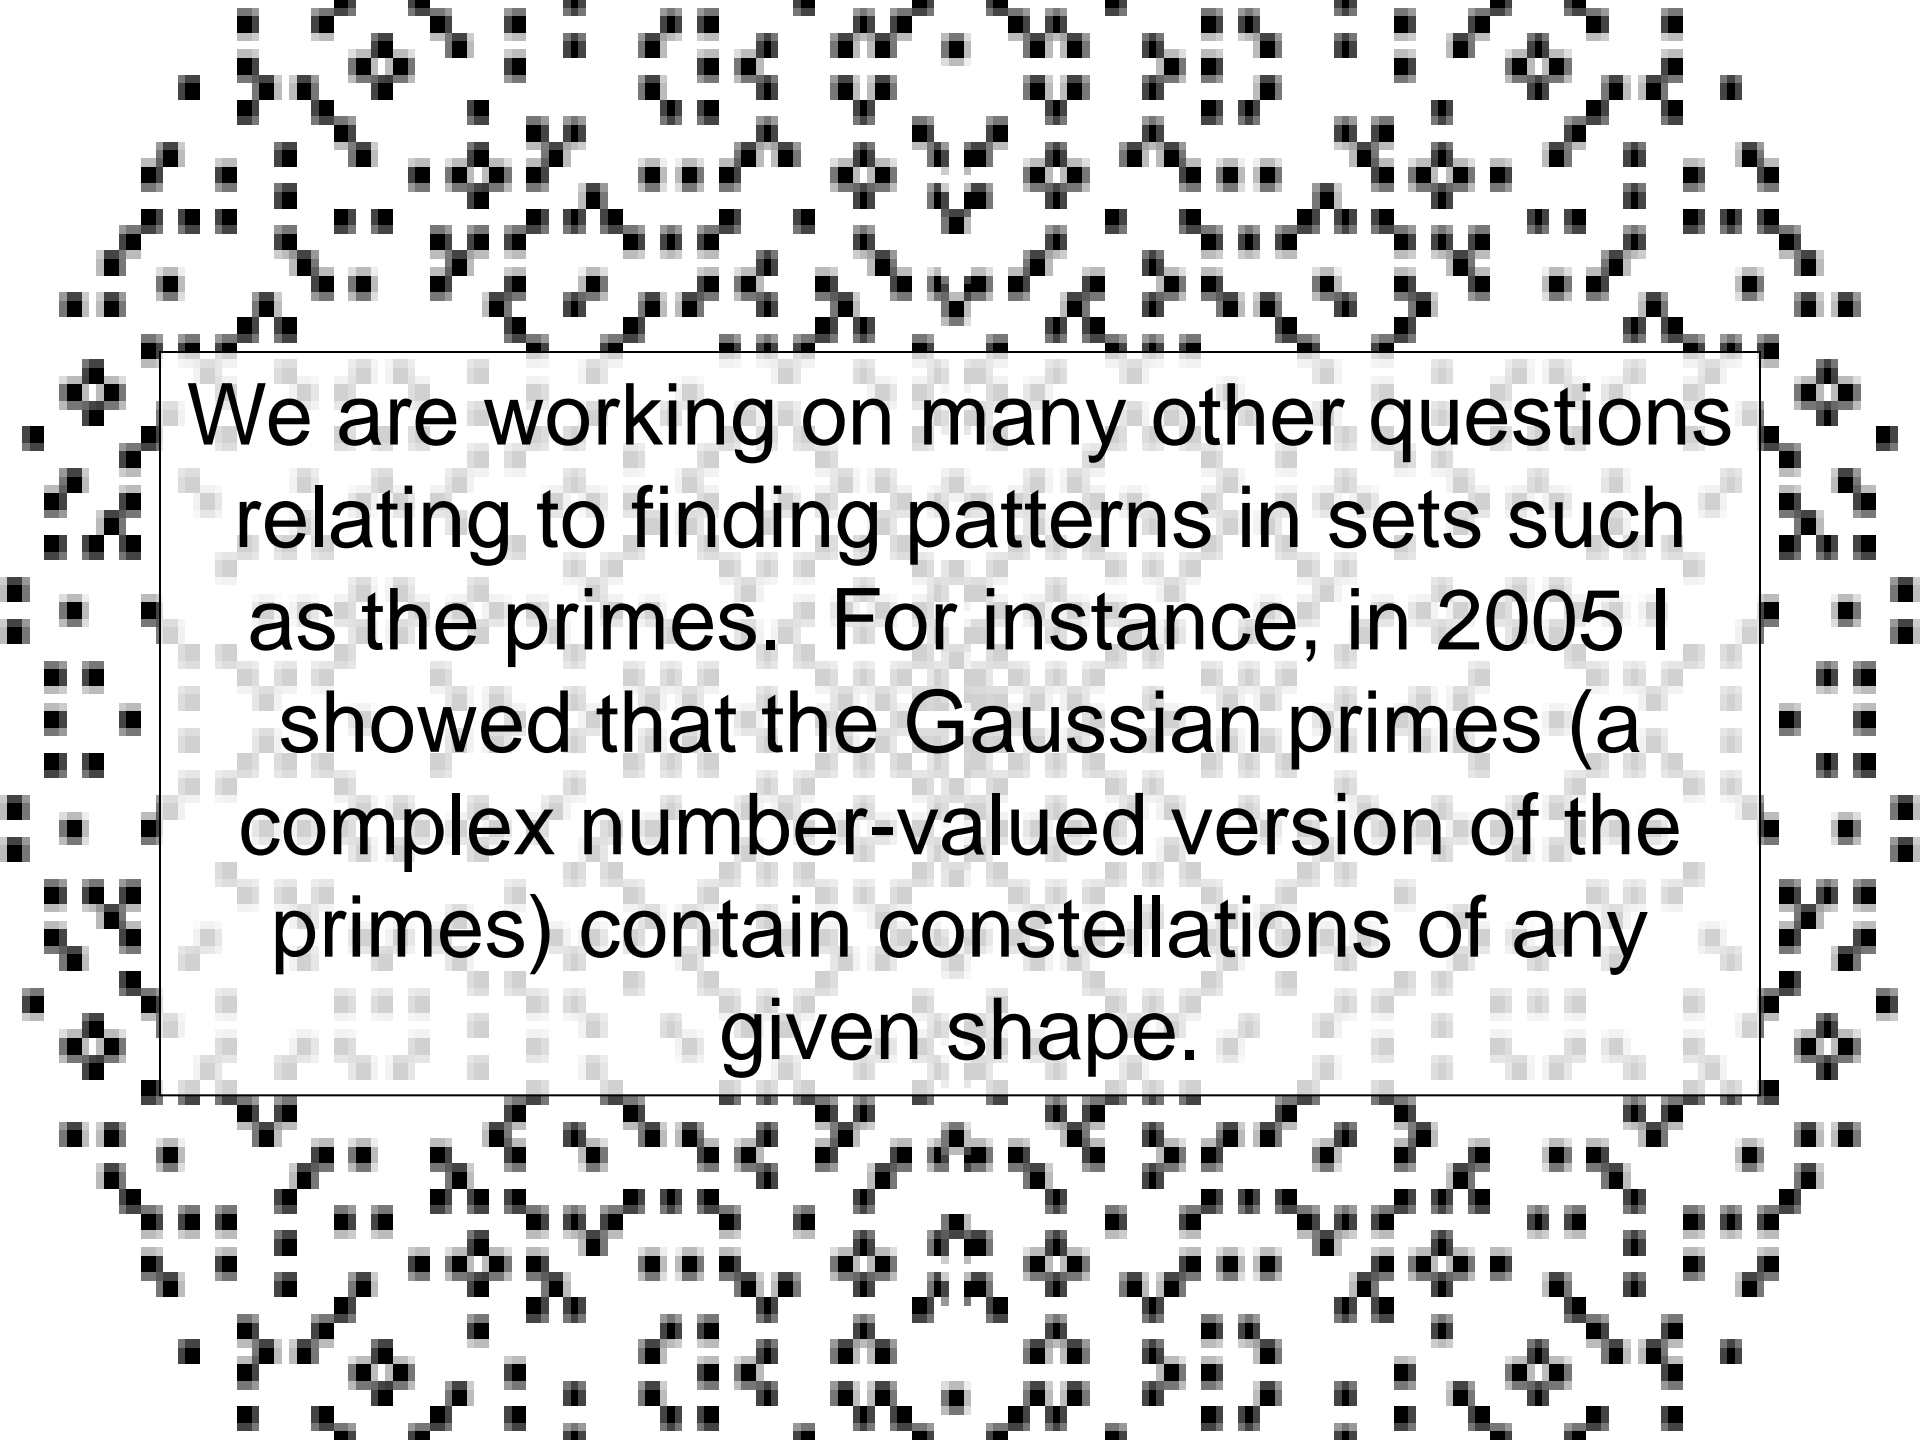

$468,395,662,504,823 + 45,872,132,836,530n$, $n=0,\dots,23$ (Wroblewski, 2007)

$6,171,054,912,832,631 + 81,737,658,082,080n$, $n=0,\dots,24$ (W.-Chermoni, 2008)

...

The proof is too technical to give here, but relies on splitting the primes into a “structured” part and a “pseudorandom” part, and showing that both components generate arithmetic progressions.

We are working on many other questions relating to finding patterns in sets such as the primes. For instance, in 2005 I showed that the Gaussian primes (a complex number-valued version of the primes) contain constellations of any given shape.
